Preface

Welcome to the Cloudbursting Manual for Bright Cluster Manager 8.2.

0.1 About This Manual

This manual is aimed at helping cluster administrators install, understand, configure, and manage the cloud capabilities of Bright Cluster Manager. The administrator is expected to be reasonably familiar with the Administrator Manual.

0.2 About The Manuals In General

Regularly updated versions of the Bright Cluster Manager 8.2 manuals are available on updated clusters by default at /cm/shared/docs/cm. The latest updates are always online at http://support.brightcomputing.com/manuals.

- The Installation Manual describes installation procedures for the basic cluster.
- The Administrator Manual describes the general management of the cluster.
- The User Manual describes the user environment and how to submit jobs for the end user.
- The Developer Manual has useful information for developers who would like to program with Bright Cluster Manager.
- The OpenStack Deployment Manual describes how to deploy OpenStack with Bright Cluster Manager.
- The Edge Manual describes how to deploy Bright Edge with Bright Cluster Manager.
- The Machine Learning Manual describes how to install and configure machine learning capabilities with Bright Cluster Manager.

If the manuals are downloaded and kept in one local directory, then in most pdf viewers, clicking on a cross-reference in one manual that refers to a section in another manual opens and displays that section in the second manual. Navigating back and forth between documents is usually possible with keystrokes or mouse clicks.

For example: <Alt>-<Backarrow> in Acrobat Reader, or clicking on the bottom leftmost navigation button of xpdf, both navigate back to the previous document.

The manuals constantly evolve to keep up with the development of the Bright Cluster Manager environment and the addition of new hardware and/or applications. The manuals also regularly incorporate customer feedback. Administrator and user input is greatly valued at Bright Computing. So any comments, suggestions or corrections will be very gratefully accepted at manuals@brightcomputing.com.

There is also a feedback form available via Bright View, via the Account icon, following the clickpath:

Account→Help→Feedback
0.3 Getting Administrator-Level Support

If the reseller from whom Bright Cluster Manager was bought offers direct support, then the reseller should be contacted. Otherwise the primary means of support is via the website https://support.brightcomputing.com. This allows the administrator to submit a support request via a web form, and opens up a trouble ticket. It is a good idea to try to use a clear subject header, since that is used as part of a reference tag as the ticket progresses. Also helpful is a good description of the issue. The followup communication for this ticket goes via standard e-mail. Section 13.2 of the Administrator Manual has more details on working with support.

0.4 Getting Professional Services

Bright Computing normally differentiates between professional services (customer asks Bright Computing to do something or asks Bright Computing to provide some service) and support (customer has a question or problem that requires an answer or resolution). Professional services can be provided after consulting with the reseller, or the Bright account manager.
Introduction

In weather, a cloudburst is used to convey the idea that a sudden flood of cloud contents takes place. In
cluster computing, the term cloudbursting conveys the idea that a flood of extra cluster capacity is made
available when needed from a cloud computing services provider such as Amazon.

Bright Cluster Manager implements cloudbursting for two scenarios:

1. A “Cluster On Demand”, or a “pure” cloud cluster (chapter 2). In this scenario, the entire cluster
can be started up on demand from a state of non-existence. All nodes, including the head node,
are instances running in a coordinated manner entirely inside the cloud computing service.

2. A “Cluster Extension”, or a “hybrid” cloud cluster (chapter 3). In this scenario, the head node
is kept outside the cloud. Zero or more regular nodes are also run outside the cloud. When
additional capacity is required, the cluster is extended via cloudbursting to make additional nodes
available from within the cloud.

Chapters 2 and 3 deal with mainly the GUI configuration of the Cluster On Demand and Cluster
Extension scenarios.

Chapter 4 looks at mainly command line tools for configuration of the Cluster On Demand and
Cluster Extension scenarios, considering mainly AWS.

Chapter 5 looks at Cluster Extension for Azure.

Chapter 6 discusses some miscellaneous aspects of cloudbursting.

Chapter 7 describes the concepts behind the networking of legacy and current cloud instances sup-
ported by Bright Cluster Manager on the Amazon VPC infrastructure.
Cluster On Demand (COD) cloudbursting is when a separate cluster is started up in a cloud, with the cluster head node that manages the cluster also in that cloud. A COD cluster is regarded as an independent virtual cluster (sometimes described as a ‘pure’ cloud cluster), and not an extension of an existing physical cluster.

## 2.1 Requirements For COD Cloudbursting

COD can run in Azure (COD-Azure), in AWS (COD-AWS), or in Bright OpenStack (COD-OS). This chapter discusses COD-Azure and COD-AWS. COD-OS is discussed in Chapter 6 of the OpenStack Deployment Manual.

The requirements for COD-Azure and COD-AWS are:

- a Bright Cluster Manager product key. This must be registered at the Customer Portal via the Register Product Key menu item. This key is later activated when the license is installed (Chapter 4 of the Installation Manual) on the head node. The head node and regular nodes in this case are in the cloud.

- Requirements For COD-Azure: To use Azure, an Azure account subscription is needed from Microsoft. COD cloudbursting requires the following associated Azure credentials to launch:
  
  - tenant ID
  - subscription ID
  - Client ID
  - Client Secret

A CLI-centric way to obtain these credentials requires logging into the Azure web portal using an account that has sufficient privileges. The Azure web bash console is then opened, and the subscription ID can then be listed for the account with:

Example
A service principal (sp) is now created for role-based access control create-for-rbac in Active Directory (ad), and the remaining 3 credentials can then be seen:

**Example**

```
azure@Azure:~$ az ad sp create-for-rbac --name my-temp-service-principal-for-fred
Changing "my-temp-service-principal-for-fred" to a valid URI of "http://my-temp-service-principal-for-fred", which is the required format used for service principal names
Retrying role assignment creation: 1/36
Retrying role assignment creation: 2/36
```

```
"appId": "dcf8151e-507a-11e9-a104-fa163e9854eb", ## "Client ID"
"displayName": "my-temp-service-principal-for-fred",
"name": "http://my-temp-service-principal-for-fred",
"password": "bc9f571e-fe4c-43d5-909d-4bc66796eb41", ## "Client secret"
"tenant": "8cb88849-6e18-46d6-b0fa-551a47a31681" ## Tenant ID
```

The newly-created service principal is added to the desired subscription as a contributor. The value of appID must be used as the value to the --assignee option. This gives the application sufficient permissions for the cluster to run:

**Example**

```
azure@Azure:~$ az role assignment create --assignee dcf8151e-507a-11e9-a104-fa163e9854eb --role Contributor --subscription b9e22a88-507a-11e9-9352-fa163e9854eb
```

```
"canDelegate": null,
"id": "/subscriptions/b9e22a88-507a-11e9-9352-fa163e9854eb/providers/Microsoft.Authorization/roleAssignments/1094f75c-507b-11e9-ac8f-fa163e9854eb",
"name": "1094f75c-507b-11e9-ac8f-fa163e9854eb",
"principalId": "2f899334-507b-11e9-b312-fa163e9854eb",
"roleDefinitionId": "/subscriptions/b9e22a88-507a-11e9-9352-fa163e9854eb/providers/Microsoft.Authorization/roleDefinitions/b24988ac-6180-42a0-ab88-20f7382dd24c",
"scope": "/subscriptions/b9e22a88-507a-11e9-9352-fa163e9854eb",
"type": "Microsoft.Authorization/roleAssignments"
```

The Microsoft documentation suggests that using the name instead of the subscription ID should also work. However in the version that was used at the time of writing (May 2019) this did not work, and an error 400 was displayed.

**• Requirements For COD-AWS:** To use AWS, an AWS subscription is needed from Amazon. COD cloudbursting requires the following associated AWS credentials for launch:

  - Secret Access Key: Available only once, when first generated, as described at https://docs.aws.amazon.com/general/latest/gr/aws-sec-cred-types.html#access-keys-and-secret-access-keys
2.2 COD Via Bright Computing Customer Portal

- Access Key ID: as described at https://docs.aws.amazon.com/general/latest/gr/aws-sec-cred-types.html#access-keys-and-secret-access-keys
- AWS Account ID, as described at https://docs.aws.amazon.com/general/latest/gr/acct-identifiers.html
- AWS Username: This can be either the AWS account root user (the e-mail address of the root user), or it can be an IAM username with sufficient permissions to launch the cluster.

COD cloudbursting can be configured and started up via the Bright Computing customer portal (section 2.2), or via a Docker image (section 2.3).

2.2 COD Via Bright Computing Customer Portal

The customer portal (section 2.1) has a menu option Cluster on Demand. Selecting this displays an input form (figure 2.1).
If this is filled in, then a COD can be launched in AWS or Azure. Some of the options are:

- Cloud provider
- The product key. This can be the existing key, or a new one. Using the existing one for a cluster that is already in use is not normally possible.
- The cluster name. This can be arbitrary.
• The SSH access method.
  
  – SSH public key access is recommended, and should then be pasted into the text field. Using key access disables SSH password authentication.
  
  – Alternatively, a password can be set instead. This generates a somewhat random password for SSH password authentication that is not very strong. The password should normally be changed and saved, because brute force password attacks in the AWS and Azure IP address ranges are common.

  Selecting AWS as an option presents some extra fields that are appropriate for launching an AWS COD (figure 2.2). How to obtain the values for the AWS keys is discussed in section 2.1. The default values that are in the form for the virtual machine types and sizes will work for small clusters. Other virtual machine types are documented at https://aws.amazon.com/ec2/instance-types/.
Selecting Azure as an option presents some extra fields that are appropriate for launching an Azure COD (figure 2.3). How to obtain the values for the Azure credentials is discussed in section 2.1. The default values that are in the form for the virtual machine types and sizes will work for small clusters. Other virtual machine types are documented at https://docs.microsoft.com/en-us/azure/virtual-machines/linux/sizes.
Figure 2.3: COD-Azure via customer portal: example inputs
Form submission begins the COD installation (figure 2.4).

When deployment is completed, an e-mail is sent with the details to the e-mail address that was entered in the form earlier. A final screen comes up if the installation was successful (figure 2.4).

![Figure 2.4: COD via customer portal: deployment in progress](image)

**Figure 2.5: COD via customer portal: finished deploying**

### 2.3 COD Via Docker Image

The procedure described in this section runs COD using a Docker image. The Docker instance that runs from the image can be hosted on a standalone PC that is not part of a Bright cluster, or it can be hosted on a Bright node. In this section the example uses a regular node from a Bright cluster as the Docker host.

#### 2.3.1 COD Via Docker Image—Procedure Summary

The following steps are carried out to start up the head node and regular nodes of the COD:

- A Docker host is used to pull the Bright Cluster Manager COD (Cluster On Demand) image from the Docker registry.
- The image is run in a Docker container.
- From within the instance of the image running in the container, a cloudbursting request for a COD is carried out to a cloud service provider.
• When the request completes successfully, a cluster that is running in the cloud is ready for use. These steps are now covered in more detail.

2.3.2 COD Via Docker Image—Procedure Details

A COD can be launched from a Bright COD Docker image running inside Docker. This is typically run from a standalone machine, such as, for example, a laptop that is not part of a Bright cluster. However, launching a COD from a Bright cluster is also possible, and can be carried out as follows:

• Docker is installed in Bright Cluster Manager with cm-docker-setup (section 9.1.1 of the Administrator Manual), or using the Bright View Docker setup wizard.

• The node that is to run the Docker image is used to pull the image to the node

Example

```
[root@bright82 ~]# ssh node001
[root@node001 ~]# module load docker
[root@node001 ~]# docker pull brightcomputing/cod:latest
... cac16ba059ef: Pull complete
Digest: sha256:19b26303090e1a70043989decdf3c870d3def8c2e69b2a85ac293fd7d149ab
Status: Downloaded newer image for brightcomputing/cod:latest
```

• The appropriate image ID can be found. For example:

Example

```
[root@node001 ~]# docker images
REPOSITORY TAG IMAGE ID CREATED SIZE
brightcomputing/cod latest aeddb120e78f 5 hours ago 593 MB
```

• The image can be run in a Docker container. This is done by running the image by specifying the ID from the preceding output. The image can run interactively with, for example:

Example

```
[root@node001 ~]# docker run -it aeddb120e78f /bin/bash
[root@256ac248b583 /]#
```

• In that container an existing SSH public key should be saved, so that it can be specified as an option to the COD cluster creation command. The associated private key should be located on any machine that is to be used to access the COD via SSH. Instead of using an existing SSH key pair, it may be convenient to generate a completely new key pair within the container, using ssh-keygen. In that case, the following may have to be borne in mind:

- If exiting from the container, then returning to that container is possible after restarting and attaching to the container again, so that the keys to the cluster remain accessible.
- However, if the container is to be removed, then a copy of the keys, or at least the private key, should exist outside the container, so that the cluster can still be accessed. For example the keys can be displayed with the cat command and then copied and pasted (some text elided):
Example

```
[root@256ac248b583 ~]# cat /root/.ssh/id_rsa
-----BEGIN RSA PRIVATE KEY-----
...
-----END RSA PRIVATE KEY-----
[root@256ac248b583 ~]# cat /root/.ssh/id_rsa.pub
ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAABAQDOXPZUImfrolTHJQ75DepyCQ...
```

It is a good idea for the administrator to plan key management, in order to minimize the spread of
the private key in general, and to manage keys in a way that works well with the work flow and
use.

Up to this point, the preparation for running a COD from Docker has been the same for whether
Azure or AWS are to be used as the cloud provider. The next stage is to launch the COD inside the cloud
service.

There are two cloud services that a COD from Docker can be launched into. These are:

- **AWS (Amazon Web Services)**, made available by Amazon. The CLI utility in the Docker instance
  that launches the COD is then `cm-cod-aws` (page 16).

- **Azure**, made available by Microsoft. The CLI utility in the Docker instance that launches the COD
  is then `cm-cod-azure` (page 12).

For completeness, a non-Dockerized COD can also be launched into the Bright OpenStack private
cloud service. The Bright OpenStack private cloud service is a cloud service that can be provided with
the Bright OpenStack edition of Bright Cluster Manager. The launch utility for this third type of COD is
`cm-cod-os`, and its use is described in detail in Chapter 6 of the *OpenStack Deployment Manual*.

**Procedure When Running `cm-cod-azure`**

Launching a COD inside Azure is carried by running `cm-cod-azure` from within the Docker container
that is outside Azure.

Running `cm-cod-azure` from within the Docker container that is outside Azure, launches a COD
within Azure.

**Options For `cm-cod-azure`:** The `cm-cod-azure` command options include the cluster name, node types,
credentials, and so on. Running `cm-cod-azure cluster create -h` displays a list of options and ex-
planations for the options.

Some of the options are described in table 2.1:
<table>
<thead>
<tr>
<th>Option</th>
<th>Example Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>--azure-client-id</td>
<td>afe13723-c80a-68e2-9cd0-e95a657106a</td>
</tr>
<tr>

...continues
...continued

<table>
<thead>
<tr>
<th>Option</th>
<th>Example Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>--license-organization</td>
<td>Illuminati</td>
</tr>
<tr>
<td>--license-unit</td>
<td>Eleusis</td>
</tr>
<tr>
<td>--license-locality</td>
<td>Munich</td>
</tr>
<tr>
<td>--license-state</td>
<td>Bavaria</td>
</tr>
<tr>
<td>--license-country</td>
<td>Germany</td>
</tr>
<tr>
<td>--license-product-key</td>
<td>12334-324234-3413413-32-324</td>
</tr>
</tbody>
</table>

The example values for the credentials given here, if used literally, will not work. They are just
to show the rough format of the values.

Table 2.1: cm-cod-azure options

The first four --azure-* options in the preceding table require the actual Azure credentials that the
cluster administrator obtains from Microsoft.

For the distinguished name values (organization, unit, and so on), the values can be arbitrary, although the administrator may find it useful to have them match the ones set in the product key license.

The verify-license utility shows the distinguished name values that were set in the product key license.

For example:

```
[root@bright82 ~]# verify-license /cm/local/apps/cmd/etc/cluster.pem /cm/local/apps/cmd/etc/cluster.key info
========= Certificate Information =========
settings for organization, unit, etc, are displayed
```

It is normally not possible to use the product key of the host cluster itself. So, normally a fresh
product key must be used with the cm-cod-azure command.

Cluster creation run with cm-cod-azure: An example of a cm-cod-azure command that can be run is:

Example

cm-cod-azure cluster create
  --azure-location 'westeurope'
  --azure-client-id 'afe13723-c80a-68e2-9cd0-e95a657106a'
  --azure-client-secret 'aiVohui7DhJ6iQim='
  --azure-tenant-id '2c89c86d-6b8b-5393-60f4-d876cbe188f'
  --azure-subscription-id '5e519b1e-aff9-e839-bc3a-c5d87e9d9d5'
  --head-node-type 'Standard_D1_v2' --head-node-root-volume-size '50'
  --nodes '3' --node-type 'Standard_D1_v2'
  --ssh-pub-key-path '/root/.ssh/id_rsa.pub'
  --license-product-key '12334-324234-3413413-32-324' 'noviceazurecluster'

If all is well, then something similar to the following is displayed (some output elided):

```
13:22:50: INFO: Credentials are valid and have read/write authorizations
```

© Bright Computing, Inc.
The cluster can now be logged into by using the SSH keys generated earlier, and using the public IP address shown in the last few lines of the preceding output.

© Bright Computing, Inc.
Listing with `cm-cod-azure`:

The clusters that are running from the container can be listed with their properties, using the credentials, as follows:

**Example**

```
[root@743d346dca20 /]# cm-cod-azure cluster list
--azure-location 'westeurope'
--azure-client-id 'afe13723-c80a-68e2-9cd0-e95a657106a'
--azure-client-secret 'aiVohwi70hJ6igim=
--azure-tenant-id '2c89c8dd-66b9-5393-60f4-d876cbe188f'
--azure-subscription-id '5e519b1e-aff9-e839-bc3a-c5d87e9d0d5'
```

```
+--------------------+------------------------------+------------+------------+-...
| Cluster Name       | Head node name               | Public IP  | Location   | ...
+--------------------+------------------------------+------------+------------+-...
| noviceazurecluster | noviceazurecluster-head_node | 13.98.90.5 | westeurope | ...
+--------------------+------------------------------+------------+------------+-...
```

Removal with `cm-cod-azure`:

A cluster can be removed from the container with:

```
[root@743d346dca20 /]# cm-cod-azure cluster delete
--azure-location 'westeurope'
--azure-client-id 'afe13723-c80a-68e2-9cd0-e95a657106a'
--azure-client-secret 'aiVohwi70hJ6igim=
--azure-tenant-id '2c89c8dd-66b9-5393-60f4-d876cbe188f'
--azure-subscription-id '5e519b1e-aff9-e839-bc3a-c5d87e9d0d5'
'noviceazurecluster'
```

**Procedure When Running cm-cod-aws**

Launching a COD from within AWS is carried by running `cm-cod-aws` from within the Docker container. This process is similar to that of launching within Azure (page 16).

**Options For cm-cod-aws:**

The `cm-cod-aws` command takes options to create a cluster. Running `cm-cod-aws cluster create -h` displays a list of options and explanations for the options.

Some of the options are described in table 2.2:

**Table 2.2: cm-cod-aws options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Example Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--aws-region</code></td>
<td>eu-central-1</td>
</tr>
<tr>
<td><code>--aws-secret-key</code></td>
<td>Oocei6eieshabG7IiJe9Quoud0oo</td>
</tr>
<tr>
<td><code>--aws-access-key-id</code></td>
<td>AKIJAICHZI70HHIEEG0</td>
</tr>
<tr>
<td><code>--head-node-type</code></td>
<td>t2.medium</td>
</tr>
<tr>
<td><code>--node-type</code></td>
<td>t2.medium</td>
</tr>
<tr>
<td><code>--license-product-key</code></td>
<td>12334-324234-3413413-32-324</td>
</tr>
<tr>
<td><code>--cluster-password</code></td>
<td>justinbieberrocks</td>
</tr>
<tr>
<td><code>--log-cluster-password</code></td>
<td><em>does not take a value</em></td>
</tr>
<tr>
<td><code>--ssh-pub-key-path</code></td>
<td>/root/.ssh/id_rsa.pub</td>
</tr>
</tbody>
</table>

...continues
The example values for the credentials given here, if used literally, will not work. They are just to show the rough format of the values.

The `--aws-secret-key` and `--aws-access-key-id` options in the preceding table require the actual AWS credentials that the cluster administrator obtains from Amazon.

Setting a root password via the `--cluster-password` option is a possible way to configure a login to the cluster. Another possibility is to use ssh keys. The keys generated within the docker instance using `ssh-keygen` earlier on can be used for this.

The password can be seen in the logs of the command if the `--log-cluster-password` option is used.

If the root password is not set with `--cluster-password`, then a random password is set, and ssh keys can be used to login to the cluster. A root password can always be specified later using `cm-change-password`, after logging into the cluster via ssh key access or the root password. The default login to Bright View also uses the root password.

For the product key of cluster in AWS, it is normally not possible to use the product key of the host cluster itself. So, normally a fresh product key must be used with the `cm-cod-azure` command.

**Cluster creation run with cm-cod-aws**: An example of a cm-cod-aws command that can be run is then:

**Example**

cm-cod-aws cluster create
  --aws-region 'eu-central'
  --aws-secret-key 'Oocei6eiieshahG7Iije9Quoud0oo'
  --aws-access-key-id 'AKIAJAICHAZI7OHH1EEGO'
  --nodes '3' --node-type 't2.medium'
  --ssh-pub-key-path '/root/.ssh/id_rsa.pub'
  --license-product-key '12334-324234-3413413-32-324' 'noobawscluster'

If all is well, then the output is similar to (some output elided):

```
12:06:57: INFO: ---------------------------------------------------------------------
12:06:57: INFO: Cluster: noobawscluster
12:06:57: INFO: ---------------------------------------------------------------------
12:06:57: INFO: Image date: 2018-02-26 16:10 (27d 19h ago)
12:06:57: INFO: Head nodes: 1 (t2.medium)
12:06:57: INFO: Nodes: 5 (t2.medium)
12:06:57: INFO: Region: eu-west-1
12:06:57: INFO: ---------------------------------------------------------------------
Press ENTER to continue and create the cluster.
Press ctrl+c (or type 'a') to abort. Type 'i' for more info.
```

© Bright Computing, Inc.
At this point, the head node running on AWS is ready for use. It can be accessed via ssh, as suggested in the last line of the preceding output.

The regular nodes running on AWS are configured for use, but are not powered on. They can be powered on using the cmsh or Bright View front ends, just as in a regular cluster.

From cmsh, the first cloud node can be powered on with, for example:

```
[noobawscluster->device]% power on cnode001
```

**Listing with cm-cod-aws:** The clusters that are running from the container can be listed with their properties, using the credentials with the region, as follows:

**Example**

```
[root@743d346dca20 ~]# cm-cod-aws cluster list
   --aws-region 'eu-west-1'
   --aws-secret-key 'Oocei6eiieshahG7IiJe9Quoud0oo'
   --aws-access-key-id 'AKIAJAICHAZI7OHH1EEGO'
   --license-product-key '12334-324234-3413413-32-324'
   +-------------------+----------------+----------------+
   | Cluster Name      | Head node name | VPC ID  |
   +-------------------+----------------+----------------+
   | noobawscluster    | noobawscluster-head_node | vpc-as89ada |
   +-------------------+----------------+----------------+
```

© Bright Computing, Inc.
Using The AWS EC2 Management Console

The recommended way of managing COD is using Bright View via its public IP address, or by using cmsh via the head node (section 2.4.5). This section (section 2.4) describes how the Amazon management console can also be used, to manage some AWS aspects of the instance.

A login is possible from https://console.aws.amazon.com/console/ by using the e-mail address and password of the associated AWS root account, or AWS IAM user account.

The head node instance can be watched and managed without Bright Cluster Manager in the following ways.

Status Checking Via Instance Selection From Instances List

Clicking the Instances menu resource item from the navigation pane opens up the “Instances” pane. This lists instances belonging to the account owner. An instance can be marked by ticking its checkbox. Information for the selected instance is then displayed in the lower main pane (figure 2.6).

Figure 2.6: The EC2 Instances List

© Bright Computing, Inc.
reachabilities are similarly shown under the neighboring “Status Checks” tab (figure 2.7).

2.4.2 Acting On An Instance From The AWS EC2 Management Console
An instance can be marked by clicking on it. Clicking the Actions button near the top of the main center pane, or equivalently from a right-mouse-button click in the pane, brings up a menu of possible actions. These actions can be executed on the marked instance, and include the options to Start, Stop or Terminate the instance.

2.4.3 Connecting To An Instance From The AWS EC2 Management Console
A marked and running instance can have an SSH connection made to it.

As in the Azure case, for most users this means running ssh to the public IP address as suggested at the end of the AWS COD cluster creation run (page 17). This is assuming the private ssh key that was generated by the ssh-keygen command in the container is used for the ssh connection, which may mean that copying it out of the container is needed.

2.4.4 Viewing The Head Node Console
The head node takes about 2 minutes to start up. If, on following the instructions, an SSH connection cannot be made, then it can be worth checking the head node system log to check if the head node has started up correctly. The log is displayed on right-clicking on the “Actions” button, selecting the Instance Settings sub-menu, and selecting the “Get System Log” menu item (figure 2.8). A successful start of the system generates a log with a tail similar to that of figure 2.8.
2.4 Using The AWS EC2 Management Console

2.4.5 Security Group Configuration To Allow Access To The Headnode Via cmsh Or Bright View

Amazon provides a security group to each instance. By default, this configures network access so that only inbound SSH connections are allowed from outside the cloud. A new security group can be configured, or an existing one modified, using the Edit details button in figure 2.9. Security groups can also be accessed from the navigation menu on the left side of the EC2 Management Console.

COD With AWS: Access With Bright View:
The security group defined by Amazon for the head node can be modified by the administrator to allow remote connections to CMDaemon running on the head node (figure 2.9).

A screenshot of the instance is also possible by right-clicking on the selected instance, then following the clickpath Instance Settings → Get Instance Screenshot.
Figure 2.9: Security Group Network And Port Access Restriction

- To allow only a specific network block to access the instance, the network from which remote connections are allowed can be specified in CIDR format.

- By default, port 8081 is open on the head node to allow Bright View (section 2.4 of the Administrator Manual) to connect to the head node. This is because the Bright View back end, which is CMDaemon, communicates via port 8081.

COD With AWS: Access With A Local csh:
The security group created by Amazon by default already allows inbound SSH connections from outside the cloud to the instance running in the cloud, even if the incoming port 8081 is blocked. Launching a csh session within an SSH connection running to the head node is therefore possible, and should work without lag.

2.5 Using The Azure Dashboard
For Azure, as is the case for AWS, the cluster is normally expected to be managed via Bright View or csh. Sometimes when carrying out some special configurations, there may be a need to manage the cluster objects directly via the portal at https://portal.azure.com. This requires an Azure login and password, which opens up the Azure dashboard, and allows the objects to be viewed and managed.

For example, the virtual machines of the COD can be viewed and managed via the Virtual machines resource (figure 2.10), and the virtual networks associated with the COD nodes can similarly be viewed and managed via Virtual networks resource.
2.6 COD: Cloud Node Start-up

Cloud nodes must be explicitly started up. This is done by powering them up, assuming the associated cloud node objects exist. The cloud node objects are typically specified in the `cm-cod-aws` or `cm-cod-azure` script which is run in the Docker instance. In the preceding example the cloud node objects are `cnode001` and `cnode002`.

However, more cloud node objects can be created if needed after the scripts have run. The maximum number that may be created is set by the license purchased.

Large numbers of cloud node objects can be created with Bright Cluster Manager as follows:

- In Bright View they can conveniently be cloned via the clickpath:
  
  Cloud → Cloud Nodes → `<cloud node>` → Clone → `<number>`

- In `cmsh` a large number of cloud node objects can conveniently be created with the “`foreach --clone`” command instead, as described in section 4.2.

After creation, an individual cloud node, `<cloud node>`, can be powered up from within Bright View via the clickpath:

Cloud → Cloud Nodes → `<cloud node>` → Power → On

© Bright Computing, Inc.
As with regular non-cloud nodes, cloud nodes can also be powered up from within the device mode of cmsh. The initial power status (section 4.1 of the Administrator Manual) of cloud nodes is FAILED, because they cannot be communicated with. As they start up, their power status changes to OFF, and then to ON. Some time after that they are connected to the cluster and ready for use. The device status (as opposed to the power status) remains DOWN until it is ready for use, at which point it switches to UP:

**Example**

```
[head1->device]% power status
cloud ................. [ FAILED ] cnode001 (Cloud instance ID not set)
cloud ................. [ FAILED ] cnode002 (Cloud instance ID not set)
No power control ...... [ UNKNOWN ] head1
[head1->device]% power on -n cnode001
ccloud ................. [ ON ] cnode001
[head1->device]% power status
cloud ................. [ OFF ] cnode001 (pending)
cloud ................. [ FAILED ] cnode002 (Cloud instance ID not set)
No power control ...... [ UNKNOWN ] head1
[head1->device]% power on -n cnode002
cloud ................. [ ON ] cnode002
[head1->device]% power status
cloud ................. [ ON ] cnode001 (running)
ccloud ................. [ OFF ] cnode002 (pending)
No power control ...... [ UNKNOWN ] head1
[head1->device]% !ping -c1 cnode001
ping: unknown host cnode001
[head1->device]% !ping -c1 cnode001
PING cnode001.cm.cluster (10.234.226.155) 56(84) bytes of data.
64 bytes from cnode001.cm.cluster (10.234.226.155): icmp_seq=1 ttl=63 time=3.94 ms
```

Multiple cloud nodes can be powered up at a time in cmsh with the “power on” command using ranges and other options (section 4.2.3 of the Administrator Manual).

### 2.6.1 COD: IP Addresses In The Cloud

- The IP addresses assigned to cloud nodes on powering them up are arbitrarily scattered over the 10.0.0.0/8 network and its subnets
  - No pattern should therefore be relied upon in the addressing scheme of cloud nodes
- Shutting down and starting up head and regular cloud nodes can cause their IP address to change.
  - However, Bright Cluster Manager managing the nodes means that a regular cloud node re-establishes its connection to the cluster when it comes up, and will have the same node name as before.

### 2.7 COD With AWS: Optimizing AWS For High Performance Computing (HPC)

Optimization of cloud nodes for HPC in AWS is discussed in section 3.5.
Cluster Extension Cloudbursting

Cluster Extension cloudbursting ("hybrid" cloudbursting) in Bright Cluster Manager is the case when a cloud service provider is used to provide nodes that are in the cloud as an extension to the number of regular nodes in a cluster. Thus, the head node in a Cluster Extension configuration is always outside the cloud, and there may be some non-cloud-extension regular nodes that are outside the cloud too.

Cluster Extension cloudbursting can burst into a cloud that is running within:

- AWS (CX-AWS). This is described in Chapters 3 and 4 of the Cloudbursting Manual.
- Azure (CX-Azure). This is described in Chapter 5 of the Cloudbursting Manual.
- OpenStack (CX-OS). This is described in Chapter 7 of the OpenStack Deployment Manual.

Requirements

Cluster Extension cloudbursting requires:

- An activated cluster license.
  
  One does not simply cloudburst right away in a Cluster Extension configuration. The license must first be made active, or the attempt will fail.
  
  A check on the state of the license can be carried out with:

  **Example**

  ```
  [root@bright82 ~]# cmsh -c "main; licenseinfo"
  License Information
  ------------------------------- ----------------------------------------
  Licensee /C=US/ST=NY/L=WS/O=Bright
  Mordor/OU=Mt. Doom/CN=Bright 8.2 Cluster
  Serial Number 54750
  Start Time Mon Oct 16 01:00:00 2017
  End Time Fri Dec 31 23:59:00 2038
  Version 7.0 and above
  Edition Advanced
  Pre-paid Nodes 100
  Pay-per-use Nodes yes
  Max Accelerator Nodes 80
  Max OpenStack Nodes 70
  Node Count 6
  Allow edge sites Yes
  Accelerator Node Count 6
  OpenStack Node Count 0
  MAC Address / Cloud ID FA:16:3E:85:C7:62
  ```
The value of End Time, Pre-paid Nodes, and Pay-per-use Nodes in the preceding license should be checked. Pre-paid nodes are nodes that may be started without incurring any additional charges. Pay-per-use nodes are nodes that incur additional charges when started. Both pre-paid and pay-per-use can be on-premise or off-premise. That is, both kinds can be used for cluster extension cloudbursting.

If activation is indeed needed, then simply running the request-license command with the product key should in most cases provide activation. Further details on activating the license are given in Chapter 4 of the Administrator Manual.

- **Registration of the product key.**
  The product key is submitted at the Customer Portal website specifically for a Cluster Extension setup, from the Burst! menu. The customer portal account is then automatically associated with the license on the head node.
  By default, registration enables the cluster administrator to run a cluster extension session. The settings option for the cluster in the user portal can be used to disable the cluster administrator from running a cluster extension session.

- **An Amazon account**, if the cloud provider is Amazon.

- **An Azure account**, if the cloud provider is Microsoft Azure.

- **An open UDP port.**
  By default, this is port 1194. It is used for the OpenVPN connection from the head node to the cloud and back. To use TCP, and/or ports other than 1194, the Bright Computing knowledgebase at http://kb.brightcomputing.com can be consulted using the keywords “openvpn port”.
  Outbound SSH access from the head node is also useful, but not strictly required.
  By default, the Shorewall firewall as provided by Bright Cluster Manager on the head node is configured to allow all outbound connections, but other firewalls may need to be considered too.

- **A special proxy environment configuration setting**, if an HTTP proxy is used to access the AWS or Azure APIs.
  The proxy environment configuration is carried out using the ScriptEnvironment directive (page 650 of the Administrator Manual), which is a CMDaemon directive that can be set and activated (page 635 of the Administrator Manual).
  For example, if the proxy host is my.proxy and accepting connections on port 8080 with a username my and password pass, then the setting can be specified as:

  \[
  \text{ScriptEnvironment} = \{ \text{"http.proxy=http://my:pass@my.proxy:8080", \ "https.proxy=http://my:pass@my.proxy:8080", \ "ftp.proxy=http://my:pass@my.proxy:8080" \}\}
  \]

**Steps**

Cluster Extension cloudbursting uses a cloud director. A cloud director is a specially connected cloud node used to manage regular cloud nodes, and is described more thoroughly in section 3.2. Assuming the administrator has ownership of a cloud provider account, the following steps can be followed to launch Cluster Extension cloud nodes:

1. The cloud provider is logged into from Bright View, and a cloud director is configured (section 3.1).
2. The cloud director is started up (section 3.2).
3. The cloud nodes are provisioned from the cloud director (section 3.3).

The cloud nodes then become available for general use by the cluster.

**Cluster Extension Cloudbursting With A Hardware VPN**

Bright Cluster Manager recommends, and provides, OpenVPN by default for Cluster Extension cloudbursting VPN connectivity. If there is a wish to use a hardware VPN, for example if there is an existing hardware VPN network already in use at the deployment site, then Bright Cluster Manager can optionally be configured to work with the hardware VPN. The configuration details can be found in the Bright Computing knowledgebase at http://kb.brightcomputing.com by carrying out a search on the site using the keywords “cloudbursting without openvpn”.

### 3.1 Cluster Extension With AWS: The Bright View Cluster Extension Wizard

Cluster Extension with the Bright View cluster extension wizard is described in sections 3.1, 3.2, and 3.3. Cluster Extension with Azure is described in Chapter 5.

The Amazon cloud service can be configured for Cluster Extension from Bright View. This can be done via the URL https://<head node address>:8081/bright-view/, and then selecting the clickpath Cloud→AWS→AWS Wizard. A screen introducing the AWS Wizard is then displayed.

The wizard goes through the following stages:

1. Introduction (section 3.1.1)
2. AWS Credentials (section 3.1.2)
3. Select Regions (section 3.1.3)
4. Summary & Deployment (section 3.1.5)
5. Deploy (section 3.1.6)

#### 3.1.1 Introduction

The first screen displayed by the wizard is the introduction screen (figure 3.1), which reminds the administrator about the prerequisites for cloudbursting.
The Show, Save, and Load buttons allow the wizard to show, save, or load a YAML configuration text file. Saving a configuration at the start or end of a wizard run is usually convenient for an administrator.

### 3.1.2 AWS Credentials

The Next button brings up the credentials page, if the credentials for the cluster extension cloudburst are not yet known to CMDaemon (figure 3.2).

![AWS Credentials](image)

**Figure 3.2: AWS Key Configuration For Cluster Extension With Bright View**

This asks for:
3.1 Cluster Extension With AWS: The Bright View Cluster Extension Wizard

- **Provider Name**: This is can be any user-defined value. If using Amazon, it would be sensible to just put in `amazon`.

- **AWS Access key ID**: The AWS Access key. Typically a string that is a mixture of upper case letters and numbers.

- **AWS Secret key**: The AWS secret key. Typically a longer string made up of alphanumeric characters.

In the case of Amazon, the information is obtainable after signing up for Amazon Web Services (AWS) at [https://console.aws.amazon.com/iam/home?#security_credential](https://console.aws.amazon.com/iam/home?#security_credential). The `Validate` button validates the credentials at this point of the configuration when clicked, instead of waiting until the actual deployment. Clicking the `Next` button submits the details of this screen, and inputs for the next screen are then retrieved from Amazon.

### 3.1.3 Select Regions

If all goes well, the next screen (figure 3.3) displays region selection options for the Amazon cloud service.

![Select Regions](image)

Figure 3.3: Selecting Regions For The Cluster Extension Wizard With Bright View

Regions are designated by codes, for example `us-east-1`, `eu-west-1`, and so on. The following are implied by the first two letters associated with the region:

- **us**: United States
- **eu**: Europe
- **ap**: Asia Pacific

© Bright Computing, Inc.
• sa: South America
• ca: Canada

In addition, the special us-gov prefix designates a region that helps customers comply with US government regulations.

Similarly, European data regulations may, for example, mean that data should be processed only within an eu region.

Other than legislative considerations, choosing capacity from a region that is geographically closer is often sensible for avoiding lag with certain applications. On the other hand, using off-peak capacity from a geographically distant location may make more sense if it is cheaper.

After the administrator has selected the regions that are to be used in deployment, the Next button can be clicked, to bring up the next screen.

### 3.1.4 Select Software Images

The Select Software Images screen (figure 3.4) lets the administrator select possible software images for the cloud director and for the cloud nodes. The cloud director virtual hardware type and cloud node virtual hardware type can also be selected in this screen.

![Select Software Images](image)

Figure 3.4: Selecting Software Images The Cluster Extension Wizard With Bright View

### 3.1.5 Summary & Deployment

The next screen is a Summary screen (figure 3.5).
3.1 Cluster Extension With AWS: The Bright View Cluster Extension Wizard

Figure 3.5: Summary Screen For The Cluster Extension Wizard With Bright View

It summarizes the selections that have been made, and lets the administrator review them. The selections can be changed, if needed, by going back to the previous screens, by directly clicking on the values. Otherwise, on clicking the Deploy button, the configuration is deployed.

3.1.6 Deploy
During configuration deployment, a progress meter indicates what is happening as the configuration is processed. At the end of processing, the display indicates with the Deployed with success message that the cluster has been extended successfully (figure 3.6).
No nodes are activated yet within the cloud provider service. To start them up, the components of the cloud provider service must be started up by

- powering up the cloud directors (section 3.2)
- powering on the cloud nodes after the cloud directors are up. Often this involves creating new cloud nodes (section 3.3).

### 3.2 Cluster Extension With AWS: Cloud Director Startup From Scratch

The cloud director can take some time to start up the first time when it is *installing from scratch*. The bottleneck is usually due to several provisioning stages, where the bandwidth between the head node and the cloud director means that the provisioning runs typically take tens of minutes to complete. The progress of the cloud director can be followed in the Bright View event log viewer (section 12.2.11 of the *Administrator Manual*), or they can be followed in an open cmsh session, as the events are sent to the cmsh session.

The bottleneck is one of the reasons why the cloud director is put in the cloud in the first place: nodes are provisioned from a cloud director in the cloud faster than from a head node outside the cloud.

The bottleneck of provisioning from the head node to the cloud director is an issue only the first time around. The next time the cloud director powers up, and assuming persistent storage is used—as is the default—the cloud director runs through the provisioning stages much faster, and completes within a few minutes.

The reason why powering up after the first time is faster is because the image that is to power up is already in the cloud. A similar principle—of relying on data already available with the cloud provider—can be used as a technique to make first time startup even faster. The technique is to have a pre-built
image—a snapshot—of the cloud director stored already with the cloud provider. The first-time startup of a cloud director based on a snapshot restoration is discussed in section 3.4.

The remainder of this section is about starting up a cloud director from scratch—that is, a first time start, and without a pre-built image.

To recap: by default, a cloud director object is created during a run of the Cluster Extension wizard (section 3.1).

There can be only one cloud director per region. Because a cloud director also has properties specific to the region within which it directs nodes, it means that cloud directors can only be created from scratch, via cluster extension.

Once a cloud director object has been made in CMDaemon, then the cloud director is ready to be started up. In Bright View the cloud director can be started by powering it up from its node settings, just like a regular node. If the cloud director node is not visible, then a browser refresh should clear up the cache so that it becomes visible. For the cloud director a clickpath to power it up is:

Cloud → Cloud Nodes → Cloud director → Power → On

As indicated earlier on, the cloud director acts as a helper instance in the cloud. It provides some of the functions of the head node within the cloud, in order to speed up communications and ensure greater resource efficiency. Amongst the functions the cloud director provides are:

- Cloud nodes provisioning
- Exporting a copy of the shared directory `/cm/shared` to the cloud nodes so that they can mount it
- Providing routing services using an OpenVPN server. While cloud nodes within a region communicate directly with each other, cloud nodes in one region use the OpenVPN server of their cloud director to communicate with the other cloud regions and to communicate with the head node of the cluster.

Cloud directors are not regular nodes, so they have their own category, cloud-director, into which they are placed by default.

The cloud-related properties of the cloud director can be viewed and edited via the clickpath:

Cloud → Cloud Nodes → Cloud director → Edit

### 3.2.1 Setting The Cloud Director Disk Storage Device Type

Amazon provides two kinds of storage types as part of EC2:

1. **Instance storage**, using so-called ephemeral devices. Ephemeral means that the device is temporary, and means that whatever is placed on it is lost if the instance is stopped, terminated, or if the underlying disk drive fails.

   Some instances have ephemeral storage associated with the instance type. For example, at the time of writing (May 2017), the m3.medium type of instance has 4GB of SSD storage associated with it. Details on instance storage can be found at [http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/InstanceStorage.html#instance-store-volumes](http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/InstanceStorage.html#instance-store-volumes).

2. **Elastic Block Storage (EBS) volumes**: EBS is a persistent, reliable, and highly available storage. Normally, EBS is suggested for cloud director and cloud node use. The reasons for this include:

   - it can be provided to all nodes in the same availability zone
   - unlike instance storage, EBS remains available for use when an instance using it is stopped or terminated.
   - instance storage is not available for many instance types such as t2.micro, t2.small, c4.large.
Using The Ephemeral Device As The Drive For The Cloud Director:

Since the cloud provider instance type is essential, and contains so much data, it is rare to use ephemeral devices as the drive for the cloud provider.

However, if for some reason the administrator would like to avoid using EBS, and use the instance storage, then this can be done by removing the default EBS volume suggestion for the cloud director provided by Bright Cluster Manager. When doing this, the ephemeral device that is used as the replacement must be renamed. It must take over the name that the EBS volume device had before it was removed.

- In Bright View, this can be done in the EC2 Storages window, which for a clouddirector <cloud director hostname> can be viewed and modified via the clickpath:

  Cloud→Cloud Nodes→<cloud director hostname>→Edit→Cloud settings→Storage→Edit

- In cmsh, this can be done in device mode, by going into the cloudsettings submode for the cloud director, and then going a level deeper into the storage submode. Within the storage submode, the list command shows the values of the storage devices associated with the cloud director. The values can be modified as required with the usual object commands. The set command can be used to modify the values.

Example

```
[bright82]% device use us-east-1-director  
[bright82->device[us-east-1-director]]% cloudsettings
[bright82->device[us-east-1-director]]% cloudsettings->storage % list
Type   Name (key)  Drive  Size   Volume ID
---------- ------------ --------- ------- ----------
ebs          ebs   sdb   42GB      
ephemeral      ephemeral0  sdc   0B  ephemeral0
[bright82->...->cloudsettings->storage]% remove ebs
[bright82->...->cloudsettings-*->storage*]% set ephemeral0 drive sdb
[bright82->...->cloudsettings-*->storage*]% list
Type   Name (key)  Drive  Size   Volume ID
---------- ------------ --------- ------- ----------
ephemeral      ephemeral0  sdb   0B  ephemeral0
[bright82->...->cloudsettings-*->storage*]% commit
```

3.2.2 Setting The Cloud Director Disk Size

The disk size for the cloud director can be set in Bright View using the EC2 Storages window (section 3.2.1).

By default, an EBS volume size of 42GB is suggested. This is as for a standard node layout (section D.3 of the Administrator Manual), and no use is then made of the ephemeral device.

42GB on its own is unlikely to be enough for most purposes other than running basic hello world tests. In actual use, the most important considerations are likely to be that the cloud director should have enough space for:

- the user home directories (under /home/)
- the cluster manager shared directory contents, (under /cm/shared/)
- the software image directories (under /cm/images/)
The cluster administrator should therefore properly consider the allocation of space, and decide if the disk layout should be modified. An example of how to access the disk setup XML file to modify the disk layout is given in section 3.9.3 of the Administrator Manual.

For the cloud director, an additional sensible option may be to place /tmp and the swap space on an ephemeral device, by appropriately modifying the XML layout for the cloud director.

3.2.3 Tracking Cloud Director Startup

Tracking Cloud Director Startup From The EC2 Management Console

The boot progress of the cloud director <cloud director> can be followed by watching the status of the instance in the Amazon EC2 management console, as illustrated in figure 2.7. The Instance ID that is used to identify the instance can be found

- with Bright View, within the clickpath
  Cloud → Cloud Nodes → <cloud director> → Edit → Cloud settings → Instance ID

- with cmsh, by running something like:

  Example

  [bright82] % device use us-east-1-director
  [bright82->device[us-east-1-director]] % get cloudid
  i-f9be7441
  [bright82->device[us-east-1-director]] % cloudsettings
  [bright82->device[us-east-1-director]-cloudsettings] % get instanceid
  i-f9be7441

Tracking Cloud Director Startup From Bright View

The boot progress of the cloud director can also be followed by

- watching the icon changes for the cloud node states in the clickpath Cloud → Cloud Nodes. The icons indicating the state follow the description given in section 5.5.1 of the Administrator Manual

Tracking Cloud Director Startup From The Bash Shell Of The Head Node

There are some further possibilities to view the progress of the cloud director after it has reached at least the initrd stage. These possibilities include:

- an SSH connection to the cloud director can be made during the pre-init, initrd stage, after the cloud director system has been set up via an rsync. This allows a login to the node-installer shell.

- an SSH connection to the cloud director can be also be made after the initrd stage has ended, after the init process runs making an SSH daemon available again. This allows a login on the cloud director when it is fully up.

During the initrd stage, the cloud director is provisioned first. The cloud node image(s) and shared directory are then provisioned on the cloud director, still within the initrd stage. To see what rsync is supplying to the cloud director, the command “ps uww -C rsync” can be run on the head node. Its output can then be parsed to make obvious the source and target directories currently being transferred:

Example

[root@bright82 ~]# ps uww -C rsync | grep -o ' /cm/.*$'
/cm/shared/ syncer@172.21.255.251::target//cm/shared/
Tracking Cloud Director Startup From cmsh

The `provisioningstatus` command in cmsh can be used to view the provisioning status (some output elided):

**Example**

```
[root@bright82 ~]# cmsh -c "softwareimage provisioningstatus"
...
+ us-east-1-director
...
  Up to date images: none
  Out of date images: default-image
```

In the preceding output, the absence of an entry for "Up to date images" shows that the cloud director does not yet have an image that it can provision to the cloud nodes. After some time, the last few lines of output should change to something like:

**Example**

```
+ us-east-1-director
...
  Up to date images: default-image
```

This indicates the image for the cloud nodes is now ready.

With the `-a` option, the `provisioningstatus -a` command gives details that may be helpful. For example, while the cloud director is having the default software image placed on it for provisioning purposes, the source and destination paths are `/cm/images/default-image`:

**Example**

```
[root@bright82 ~]# cmsh -c "softwareimage provisioningstatus -a"
Request ID(s): 4
Source node: bright82
Source path: /cm/images/default-image
Destination node: us-east-1-director
Destination path: /cm/images/default-image
...
```

After some time, when the shared filesystem is being provisioned, the source and destination paths should change to the `/cm/shared` directory:

```
[root@bright82 ~]# cmsh -c "softwareimage provisioningstatus -a"
Request ID(s): 5
Source node: bright82
Source path: /cm/shared
Destination node: us-east-1-director
Destination path: /cm/shared
...
```

After the shared directory and the cloud node software images are provisioned, the cloud director is fully up. Cloud node instances can then be powered up and provisioned from the cloud director.

© Bright Computing, Inc.
3.3 Cluster Extension With AWS: Cloud Node Startup From Scratch

This section discusses the configuration of regular cloud node startup from scratch. Configuration of cloud node startup from snapshot is discussed in section 3.4. Regular cloud nodes are the cloud nodes that the cloud director starts up.

To configure the regular cloud nodes does not require a working cloud director. However to boot up the regular cloud nodes does require that the cloud director be up, and that the associated networks to the regular cloud nodes and to the head node be configured correctly.

If needed, additional cloud provisioning nodes (section 5.2 of the Administrator Manual) can be configured by assigning the provisioning role to cloud nodes, along with appropriate nodegroups (page 153 of the Administrator Manual) values, in order to create a provisioning hierarchy.

Creation and configuration of regular cloud node objects is conveniently carried out by cloning another regular cloud node from one of the default cloud nodes already created by the cluster extension wizard (section 3.1). A clickpath is:

Cloud → Cloud Nodes → <cloud node hostname> ↓ Clone

Cloud node objects can also be created in cmsh as described in section 4.2.

The internal network for the regular cloud nodes is by default set to the VPC private network, and is somewhat similar to the internal network for regular nodes. The VPC private network can be contrasted with the VPC public network for cloud directors, which is a network that is by default assigned to cloud directors, and which floating IP addresses can connect to. Both the VPC private and VPC public networks are subnets of a cloud network. If the administrator would like to do so, the regular cloud nodes can be placed in the VPC public network and become directly accessible to the public.

If the cloud director is up, then the cloud nodes can be booted up by powering them up (section 4.2 of the Administrator Manual) by category, or individually.

3.4 Cluster Extension With AWS: Cloud Director And Cloud Node Startup From Snapshots

A technique that speeds up cluster deployment in the cloud is to use snapshots to start up the nodes in the cloud. Snapshots are snapshots of a shutdown state, and are stored by the cloud provider. In Amazon, they can be stored in EBS. It is cheaper to keep a machine in a stored state, rather than have it up but idling. Restoring from a snapshot is also significantly faster than starting up from scratch, due to optimizations by the cloud provider. An administrator should therefore get around to looking at using snapshots once cloudbursting is set up and the usage pattern has become clearer.

As a part of regular maintenance, snapshot configuration can be repeated whenever cloud director and cloud node files change significantly, in order to keep usage efficiency up.

3.4.1 Cloud Director Startup From Snapshots

Cloud Director Snapshot Preparation

A cloud director, for example us-east-1-director, can have a snapshot of its state prepared as follows by the administrator:

- The cloud director is started up from scratch (section 3.2)
- After it comes up for the first time, the administrator shuts it down cleanly. For example, with a command similar to cmsh -c "device use us-east-1-director; shutdown"
- After the cloud-director shutdown is complete, the administrator creates a snapshot of a cloud director using the EC2 Management Console. This can be done by selecting Elastic Block Store in the navigator column, then selecting the Volumes item within that menu. The volume associated with the cloud director can be identified by matching the Attachment Information column value

© Bright Computing, Inc.
with the name us-east-1-director for this node, and the device to be snapshotted. In a default configuration, the device is /dev/sdb at the time of writing, but that may change. The Actions button in the main pane then provides a Create Snapshot item (figure 3.7).

Figure 3.7: Creating A Snapshot From A Selected Volume

Using it creates a snapshot of a selected volume instance via a dialog. The snapshot ID is displayed at the end of the snapshot creation dialog, and should be noted for CMDaemon use later on, where it is saved as the value of snapshotid.

Created snapshots can be viewed within the Snapshots item of the Elastic Block Store menu.

Cloud Director Launch From Prepared Snapshot
To allow CMDaemon to launch the cloud director from the snapshot, the following procedure can be followed:

- The instance must be terminated so that the snapshot can actually be used by the instance on starting it again:

  Example

  [bright82->device[us-east-1-director]]% terminate
  us-east-1-director terminated

- The snapshot ID that was noted earlier during snapshot preparation is set in the EBS storage setting configuration of the CMDaemon database, using a session similar to:

  Example

  [root@bright82 ~]# cmsh
  [bright82]% device
  [bright82->device]% use us-east-1-director
  [bright82->device[us-east-1-director]]% cloudsettings
  [bright82->...-director]->cloudsettings% storage
  [bright82->...-director]->cloudsettings->storage% use ebs
  [bright82->...-director]->cloudsettings->storage[efs]]% set snapshotid snap-2a96d0c6

© Bright Computing, Inc.
The cloud director can now be powered on:

Example

[bright82->device[us-east-1-director]]% power on

The cloud director now starts up much faster than when starting up from scratch.

### 3.4.2 Cloud Node Startup From Snapshots

When a regular cloud node is launched from scratch (section 3.3), it uses the cloud director for provisioning, rather than a node outside the cloud, because this is faster. However, having the cloud director create an EBS volume from its storage in the cloud, and then providing the image to the cloud compute nodes still involves a lot of data I/O. On the other hand, a cloud provider such as Amazon can optimize many of these steps when creating an EBS volume from a snapshot, for example, by using copy-on-write. This means that snapshot-based provisioning is even speedier than the non-snapshot, “from scratch” method.

If the administrator wants to make a snapshot that can be used as the base for speedily launching regular cloud nodes, then the same snapshot method that is used for cloud directors (section 3.4.1) should be followed to make a snapshot for a regular cloud node.

A summary of the steps that can be followed is:

- a regular cloud node is started up from scratch (section 3.3), after the cloud director is up
- after the regular cloud node has come up, it is shut down cleanly
- a snapshot is created of the cloud node using the EC2 Management Console
- the cloud node is terminated
- the snapshot ID is set:

  Example

  [bright82->device[cn001]->cloudsettings->storage[ebs]]% set snapshotid snap-5c9s3991

Powering on the node now launches the regular cloud node much faster than the non-snapshot method.

CMDaemon ensures that a snapshot for one cloud node can be used by other cloud nodes too, if the disk partitioning is the same. This is useful when launching cloud nodes that do not differ much from the snapshot.

It also means that even the cloud director image can be used as a snapshot to launch a regular cloud node, if the disk partitioning and other settings allow it. However, using a regular node snapshot for launch is usually much wiser, due to the extra filesystems that a cloud director has.

### 3.5 Cluster Extension With AWS: Optimizing AWS For High Performance Computing (HPC)

For HPC, performance is a central concern. Optimization for the jobs that are run can be carried out by the administrator considering what are the most cost-effective aspects of the system that can be improved. The considerations in this section for AWS, apply to COD instances as well as to Cluster Extension instances.
3.5.1 Optimizing HPC Performance: EBS Volume Type

The volume type used for EBS storage can be considered. AWS provides the gp2, io1, sc1, st1, and standard storage volume types. These volume types, and their associated IOPS performances, are described at https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/EBSVolumeTypes.html.

- In cmsh these can be set in the storage mode:

  Example

  [bright82->device[cnode001]->cloudsettings->storage[ebs]]% set volumetype io1

- In Bright View, the equivalent clickpath is:

  Cloud→Cloud Nodes→Settings→Cloud settings→Storage→EBS→Volume type

3.5.2 Optimizing HPC Performance: Placement Groups

The locality of the cloud nodes with respect to each other and with respect to the cluster that they extend from can be considered.

For cloud nodes in the same placement group, lag times are minimized between the nodes. For cloud nodes that are geographically near cluster that they extend from, the lag times are reduced between the cloud nodes and the cluster they extend from.

Localizing HPC cloud nodes within the same placement group is usually desirable. This can be achieved using the AWS web console to access the cluster extension AWS account. A placement group can be created for a region via the AWS web console for the instance.

The clickpath to carry this out is Services→EC2→Services→Placement Groups→Create Placement Group. A name should be set. The value of Strategy should be set to Cluster, to localize the nodes.

The same placement group name can then be set via cmsh for the not-yet-instantiated cloud nodes. Setting this means that those nodes are now started in that placement group.

Example

[bright82->device[cnode001]->cloudsettings]% set placementgroup indahood

3.5.3 Optimizing HPC Performance: Disabling Hyper-Threading

Hyper-Threading (HT) in many cases hinders HPC performance. When running cluster extension cloud nodes, HT can be left enabled on some instances and disabled on others, depending on the need.

To disable HT, the following can be inserted into the /etc/rc.local file for the cloud node image, and made executable with a chmod +x:

```
for cpunum in $(cat /sys/devices/system/cpu/cpu*/topology/thread_siblings_list | \
  cut -s -d\- -f2- | tr ',' '
' | sort -un)
do echo 0 > /sys/devices/system/cpu/cpu$cpunum/online; done;
```

The delimiter used in the cut command is "-" instead of a ",".

If HT is disabled on the cloud node, then it can be confirmed by checking the output of the lscpu -extended command (output truncated):

Example

[root@cnode001 ~]# lscpu --extended
CPU NODE SOCKET CORE L1d:L1i:L2:L3 ONLINE
0 0 0 0 0:0:0:0 yes
1 - - - :... no
...

In the line just before the "...", the "no" indicates that that logical CPU (CPU1 in this case) has been disabled.
3.5.4 Optimizing HPC Performance: Using Elastic Network Adapter Instances
Enhanced networking that is needed for some instance types is possible if the AMI used has the Elastic Network Adapter (ENA) support attribute set. By default, all AMIs provided by Bright Cluster Manager since release 8.1-9 have ENA, as provided by the ena kernel module. If this kernel module is absent, the administrator should update the AMI.

3.5.5 Optimizing HPC Performance: Using A Different Clock Source
Xen is the default clocksource on AWS. Occasionally, some applications can benefit from using the TSC clocksource. Because of this, the clock source is generally changed as a best practice. The clock source can be changed with the following command:

Example

[root@cnode001 ~]# echo "tsc" > /sys/devices/system/cl*/cl*/current_clocksource

3.5.6 Optimizing HPC Performance: Setting The Socket Buffer Sizes And TCP/IP Parameters In The Software Image
The socket and TCP/IP window values can be modified by inserting the following values into the sysct1.conf file in the image:

Example

[root@bright82 ~]# cat >> /cm/images/default-image/etc/sysctl.conf << EOF
net.core.netdev_max_backlog = 1000000

net.core.rmem_default = 124928
net.core.rmem_max = 67108864
net.core.wmem_default = 124928
net.core.wmem_max = 67108864

net.ipv4.tcp_keepalive_time = 1800
net.ipv4.tcp_mem = 12184608 16246144 24369216
net.ipv4.tcp_rmem = 4194304 8388608 67108864
net.ipv4.tcp_syn_retries = 5
net.ipv4.tcp_wmem = 4194304 8388608 67108864
EOF

4.1 The cm-cluster-extension Script For Cluster Extension Clusters

4.1.1 Running The cm-cluster-extension Script On The Head Node For Cluster Extension Clusters

The cm-cluster-extension script is run from the head node. It is a part of the Bright Cluster Manager cluster-tools package. It allows cloudbursting to be carried out entirely from the command line for Cluster Extension setups. It is a command line way of carrying out the configuration carried out by the GUI steps of section 3.1 for cloud provider login and cloud director configuration. After the script has completed its setup, then cmsh power commands can launch the required cloud nodes (sections 4.1.2 and 4.2).

The cm-cluster-extension script can be run in plain dialog mode (page 43), or as an Ncurses dialog (page 45).

Running The cm-cluster-extension Command Line Options As A Shell Dialog

The administrator can specify command line options to cm-cluster-extension, as shown in its help text. The help text is displayed with the -h|--help option:

[root@bright82 ~]# cm-cluster-extension -h
Please wait...

usage: cm-cluster-extension

[-v] [-h] [-c <config_file>]
[--skip-modules <mod1,mod2,...>]
[--only-these-modules <mod1,mod2,...>]
[--dev] [--tests]
[--undo-on-error]
[--on-error-action {debug,remotedebug,undo,abort}]
[--output-remote-execution-runner]
[--json] [--no-distro-checks]
[--remove]
[--terminate-instances]
[--force]
[--yes-i-know-this-is-dangerous-for-this-cluster <headnode_hostname>]

© Bright Computing, Inc.
Cluster Extension Cloudbursting With AWS Using The Command Line And cmsh

common:
Common arguments

-v Verbose output
-h, --help Print this screen
-c <config_file> Load runtime configuration for modules from a YAML config file

advanced:
Various *advanced* configuration options flags.

--skip-modules <mod1,mod2,...>
Load and use all the default plugins (cloudstorage, clusterextension), except for these. Comma-separated list.

--only-these-modules <mod1,mod2,...>
Out of all default plugins, load and use only these. Comma-separated list.

--dev Enables additional command line arguments

--tests Test integrity of the utility by running Unit Tests

--undo-on-error Upon encountering a critical error, instead of asking the user for a choice, setup will undo (revert) the deployment stages.

--on-error-action {debug,remotedebug,undo,abort}
Upon encountering a critical error, instead of asking the user for choice, setup will undo (revert) the deployment stages.

--output-remote-execution-runner Format output for CMDaemon

--json Use json formatting for log lines printed to stdout

--no-distro-checks Disable distribution checks based on ds.json

removing cluster extension:
Flags which can be used for removing AWS integration

--remove Remove definitions of all objects required for cluster extension, e.g. cloud nodes, directors, cloud networks and cloud interfaces

--terminate-instances Terminate all non-terminated VMs.

--force Skip interactive confirmation for --remove

--yes-i-know-this-is-dangerous-for-this-cluster <headnode_hostname>
Additional confirmation

testing cluster extension:
Flags which can be used for troubleshooting

--test-networking Perform networking checks (e.g. check if API endpoints are reachable)

--test-environment Run environment checks (e.g. if proper RPMs are installed)

--test-configuration Run configuration checks, which check if cluster extension is properly configured (e.g. if cloud director has correct interfaces, if cloud credentials are valid, if CMDaemon can create/delete objects in the cloud)

--test-everything Run all of the abovementioned checks.

examples:

© Bright Computing, Inc.
4.1 The cm-cluster-extension Script For Cluster Extension Clusters

`cm-cluster-extension` (start interactive menu, wizard)

`cm-cluster-extension -c <config>` (configure bursting to AWS)

`cm-cluster-extension --remove` (remove bursting)

`cm-cluster-extension --remove --force --yes-i-know-this-is-dangerous-for-this-cluster <hostname>` (remove bursting, no confirmation)

*WARNING* This will remove the cloud extension configuration. Any data located on your cloud nodes will be lost, unless you back it up beforehand.

`cm-cluster-extension --test-everything`

This tool looks for the following environment variables, and uses them if found:

- `AWS_USERNAME`, `AWS_ACCOUNT_ID`, `AWS_ACCESS_KEY_ID`, `AWS_SECRET_ACCESS_KEY`
- `AZURE_SUBSCRIPTION_ID`, `AZURE_TENANT_ID`, `AZURE_CLIENT_ID`, `AZURE_CLIENT_SECRET`

It can be run with the options directly (some output skipped):

**Example**

```
[root@bright82 ~]# cm-cluster-extension --test-networking
Please wait...
Found an optional config file, '/root/cm-setup.conf'. Will attempt to load it.
Executing 26 stages

Starting execution for 'Running networking checks'

Connecting to CMDaemon
- cloudstorage
- clusterextension

### stage: clusterextension: Testing tcp connection to ec2.us-east-1.amazonaws.com:443
### stage: clusterextension: Testing tcp connection to ec2.us-west-1.amazonaws.com:443
...
### stage: clusterextension: Testing udp OpenVPN connectivity

Took: 00:09 min.

Finished execution for 'Running networking checks', status: completed
```

Running networking checks finished!

**Running The cm-cluster-extension Ncurses Dialog**

The more user-friendly way to run `cm-cluster-extension` is to run it without options. This brings up the main screen for its Ncurses dialog (figure 4.1).

![Figure 4.1: Configuration Processing With cm-cluster-extension: Main Screen](image)

Cluster extension cloudbursting deployment can be carried out by selecting AWS (described in this chapter), Azure (Chapter 5), or Bright OpenStack (Chapter 7 of the OpenStack Deployment Manual), from the main screen.

After AWS is selected, a new AWS provider can be set if none is already set up. Testing only the network connectivity to the various AWS regions is also possible.
If a new AWS provider is selected, then a screen comes up asking for the credentials for Amazon (figure 4.2):

![Provide your AWS credentials](image1)

“Provider name” is a custom, human readable, string. “Access Key ID” and “Secret Key” will be verified in the next step by contacting AWS.

![AWS Access Key ID: 1Q0MNUSLUE123DRP0](image2)

Provider name: **Amazon**

AWS Access Key ID: **1Q0MNUSLUE123DRP0**

AWS Secret Key: **ra9x57d4uy12uq09h414aixuThee5sw1i6ch**

![< OK > < Back >](image3)

Figure 4.2: Configuration Processing With cm-cluster-extension: Obtaining Credentials

After checking the credentials, the initial number of cloud nodes to be set up in the cloud can be set (figure 4.3). A default of 3 is suggested.

![Provide the number of cloud nodes](image4)

Number of cloud nodes: **3**

![< OK > < Back >](image5)

Figure 4.3: Configuration Processing With cm-cluster-extension: Setting The Initial Number Of Cloud Nodes

After setting an initial number of cloud nodes, the available regions into which these can be deployed are displayed (figure 4.4):

![Please select the region(s) to which you would like to extend your cluster to.](image6)

You can always add and configure additional regions later on.

![< OK > < Back >](image7)

Figure 4.4: Configuration Processing With cm-cluster-extension: Regions Selection

After selecting one or more regions, a default instance type must be set for the regular cloud nodes.
m3.medium (3.75GB RAM, 4GB SSD, 3 EC2 compute units) is the suggested default (figure 4.5):

![Default Instance Type](image)

Figure 4.5: Configuration Processing With cm-cluster-extension: Default Instance Type

A similar default instance type screen asks for the cloud director node type, and m3.medium is again the suggested default.

The summary screen (figure 4.6) is a screen to let the administrator look things over before deployment:

![Summary Screen](image)

Figure 4.6: Configuration Processing With cm-cluster-extension: Summary Screen

The summary screen allows the following:

- An administrator can just go ahead, save the configuration, and deploy the cluster extension. This is usually the expected action.

- The configuration settings YAML file can be viewed. To scroll, the PageUp and PageDown keys are used.

- The advanced configuration settings screen can be accessed in addition to the standard settings. The advanced settings are usually left alone.

- The configuration file, `<configuration file>`, can be saved and the Ncurses dialog can be exited. By default, the value of `<configuration file>` is set to `cm-cluster-extension.conf` in the home directory of the user. On exiting the Ncurses dialog, deployment with that configuration can be carried out manually by running:

```
cm-cluster-extension -c `<configuration file>`
```

After cm-cluster-extension has carried out a successful deployment, the cloud nodes (the cloud director and regular cloud nodes) can be launched.

© Bright Computing, Inc.
4.1.2 Launching The Cloud Director For Cluster Extension Clusters

Launching the cluster in the cloud requires that the cloud director (section 3.2) and cloud nodes be powered up. This can be done using Bright View as described in sections 3.2 and 3.3. It can also be carried out in cmsh, for example, the cloud director eu-west-1-director can be powered up from device mode with:

**Example**

```cmsh
cmsh -c "device power on -n eu-west-1-director"
```

If the administrator is unsure of the exact cloud director name, one way it can easily be found is via tab-completion within the device mode of cmsh. Alternatively, the cloud directors for AWS can be listed with:

**Example**

```cmsh
cmsh -c "device; list -c aws-cloud-director"
```

As explained in section 3.2, the cloud director takes some time to power up. Its status can be followed in the notice messages sent to the cmsh session, or in the Bright View event viewer. The status can also be queried via the status command in device node. For example, a watch instruction such as:

```bash
[root@bright82 ~]# watch 'cmsh -c "device status -n eu-west-1-director"
```

will show a series of outputs similar to:

```
eu-west-1-director ........ [ PENDING ] (Waiting for instance to start)
eu-west-1-director ........ [ PENDING ] (Waiting for instance to start)
eu-west-1-director ........ [ PENDING ] (IP assigned: 54.220.240.166)
eu-west-1-director ........ [ PENDING ] (setting up tunnel)
eu-west-1-director ........ [ INSTALLER_REBOOTING ]
eu-west-1-director ........ [ INSTALLING ] (recreating partitions)
eu-west-1-director ........ [ INSTALLING ] (FULL provisioning to "/")
eu-west-1-director ........ [ INSTALLING ] (provisioning started)
eu-west-1-director [ INSTALLER_CALLINGINIT ] (switching to local root)
eu-west-1-director ........ [ UP ]
```

4.2 Launching The Cloud Nodes

Once the cloud director is up on the cloud provider, the regular cloud nodes can also be powered up. This does however first require that the corresponding cloud node objects exist. That is, that CMDaemon must have a representation of the cloud nodes, even if they do not yet exist on the cloud provider. The objects must each have an IP address assigned to them that is consistent with that of the cloud director that manages them. That is, the network address of the cloud nodes must be what the cloud director expects.

Bright Cluster Manager’s cluster extension utilities create 3 cloud node objects by default (figure 4.4, page 46). Cloning them is an easy way to extend the number of deployable cloud nodes.

With Bright View, this can be done with the `clone` command to assign properties to the clone that match the original (section 3.3), but advance the relevant IP addresses by 1. In cmsh, the `clone` command works the same way.

To launch a cloud node that has an object, a command can be run as follows:

```cmsh
[bright82->device[cnode001]->interfaces]% device power on -n cnode001
```

© Bright Computing, Inc.
4.2.1 Creating And Powering Up Many Nodes

For a large number of cloud nodes, the creation and assignment of IP addresses can be done with the clone option of the `foreach` command, (section 2.5.5 of the *Administrator Manual*), together with a node range specification. This is the same syntax as used to create non-cloud regular nodes with `cmsh`.

Earlier on in this section, starting from page 45, an Ncurses session was run that ended up creating

- the cloud director `eu-west-1-director` and
- regular node objects `eu-west-1-cnode001` up to `eu-west-1-cnode003`.

Continuing with the end result of that session, cloning many further regular cloud nodes can now be carried out by cloning `eu-west-1-cnode003`:

Example

```
bright82->device\% foreach --clone eu-west-1-cnode003 -n eu-west-1-cnode0[04-12] ()
```

Warning: The Ethernet switch settings were not cloned, and have to be set manually ... 
```
bright82->device\% commit
Successfully committed 9 Devices
```

As a reminder, the node range option `-n eu-west-1-cnode004..eu-west-1-cnode012` would also be valid for the preceding example, and perhaps easier to comprehend, although longer.

The IP addresses are assigned to the cloud nodes via heuristics based on the value of `eu-west1-cnode003` and its cloud director.

Powering up many cloud nodes can carried out using `cmsh` with the node range option as follows:

Example

```
bright82->device\% power on -n eu-west-1-cnode0[02-10]
```

4.3 Submitting Jobs With `cmsub` And Cloud Storage Nodes, For Cluster Extension Clusters

The `cmsub` command is a user command wrapper that submits job scripts to a workload manager in a Cluster Extension cluster, so that jobs are considered for running in the cloud. Its usage for an end user is covered in section 4.7 of the *User Manual*.

The `cmsub` command is available from the Bright Cluster Manager repository as part of the `cmdaemon-cmsub` package. The `cmsub` command needs the `cmsub` environment module (section 2.2 of the *Administrator Manual*) to be loaded by the end user before use. In addition, an administrator must assign the `cloudjob` profile (section 6.4 of the *Administrator Manual*) to `cmsub` users.

Example

```
[root@bright82 ~]# cmsh
[bright82]\% user use henry
[bright82->user[henry]]\% set profile cloudjob; commit
```

If the `cmsub` command is run by the user to submit a job, then the job is submitted to the workload manager, and the data-aware scheduling mechanism is initiated.

A cluster with data-aware scheduling is a cluster that ensures that it has the data needed for the cloud computing job already accessible on cloud storage nodes.

Cloud storage nodes are nodes that are set up by the cluster manager, before the job is executed in the cloud. Because data stored can be written and read from many cloud storage nodes for each job that
is placed in the cloud, the data throughput in the cloud becomes more efficient than if only one storage space were used.

Cloud storage nodes are powered up automatically if cmsub has been installed and configured. They must however be powered down explicitly, and this must be done before the cloud director that it depends on is powered down.

### 4.3.1 Installation And Configuration of cmsub For Data-aware Scheduling To The Cloud

The configuration of data-aware scheduling means configuring the cluster so that the tools that allow data-aware scheduling to work correctly are configured. The configuration that is carried out depends on the workload manager that is to be used.

If cmsub has not yet been set up, or if it needs reconfiguration, then the following steps should be carried out:

1. The `cmdaemon-cmsub` package is installed. It must be installed on the head node and in the software image that is to be used for compute cloud nodes and storage cloud nodes.

   **Example**

   ```
   [root@bright82 ~]# yum install cmdaemon-cmsub
   [...]  
   [root@bright82 ~]# yum --installroot /cm/images/default-image install cmdaemon-cmsub
   [...]  
   ```

2. The `cm-cloud-storage-setup` utility is run. Example runs are provided later, starting on page 51, but an explanatory background is given here first.

   The utility is part of the `cluster-tools` package, which is installed by default. The utility

   - configures cmsub properties
   - creates
     - templates for cloud storage nodes
     - storage policies for cmsub

**Templates For Cloud Storage Nodes And Storage Policy**

**Templates for cloud storage nodes**: are a cloud node definition associated with a cloud provider. Templates for cloud storage nodes, more conveniently called template nodes, provide a template that is used by the cloud storage nodes. Template nodes, being templates, are never powered on, and are therefore always in a Down state in cmsh and Bright View. Actual cloud storage nodes, on the other hand, can be powered on by the cluster manager, so that they can be used to store cloud job data.

In addition, any network interfaces associated with a template node can generally be regarded as non-functioning as far as the administrator is concerned. One feature of template nodes however is that the tunnel IP address set in the template is an offset to the network address that will be used to assign IP addresses to actual storage nodes.

**A storage policy**: defines other parameters for how storage for cloud jobs is handled. Its parameters include:

- **Name**: the name set for the policy
- **Bucket Name**: the S3 bucket used for cloud jobs to transfer input and output job data
- **Default job output size**: specifies the default free storage space that will be provisioned for the result that a job produces

© Bright Computing, Inc.
• Storage node name prefix: specifies a prefix for how storage nodes are to be named. The prefix is cstorage by default. The number suffix scheme is as for regular nodes. Thus, by default, the storage nodes are cstorage001, cstorage002 and so on.

• Template for cloud nodes: the template to use as the prototype for storage nodes

**Example**

**Configuration Of cmsub Properties With cm-cloud-storage**

The cm-cloud-storage-setup is an Ncurses utility that configures cmsub properties for a cloud deployment. When run with the -h|--help option its usage is displayed:

```
[root@bright82 ~]# cm-cloud-storage-setup -h
Please wait...
usage: Cloud storage setup cm-cloud-storage-setup [-v] [-h] [-c <config_file>]
       [-dev] [-tests]
       [-undo-on-error]
       [--on-error-action
           {debug,remotedebug,undo,abort}]
       [--output-remote-execution-runner]
       [--json-output <path_to_file>]
       [--play-scenario <path_to_file>]
       [--rec-scenario <path_to_file>]
       [--skip-reboot] [--remove]
```

optional arguments:

--skip-reboot Don't reboot the nodes

common:

Common arguments

-v Verbose output
-h, --help Print this screen
-c <config_file> Load runtime configuration for modules from a YAML config file

advanced:

Various *advanced* configuration options flags.

--dev Enables additional command line arguments
--tests Test integrity of the utility by running Unit Tests
--undo-on-error Upon encountering a critical error, instead of asking the user for choice, setup will undo (revert) the deployment stages.
--on-error-action {debug,remotedebug,undo,abort} Upon encountering a critical error, instead of asking the user for choice, setup will undo (revert) the deployment stages.
--output-remote-execution-runner Format output for CMDaemon
--json-output <path_to_file> Generate a file containing json-formatted summary of the deployment
--play-scenario <path_to_file> Reproduce wizard scenario recorded before
--rec-scenario <path_to_file> Record wizard scenario

Remove storage:

--remove Cleanup storage setup

© Bright Computing, Inc.
The administrator is usually expected to run `cm-cloud-storage-setup` without arguments. This brings up the Ncurses-based dialog, which starts with an introductory page (figure 4.7):

![Image of Cloud Storage Configuration Processing With cm-cloud-storage: Main Screen](image1.png)

Figure 4.7: Cloud Storage Configuration Processing With cm-cloud-storage: Main Screen

Continuing on brings up the network selection screen, which sets the network in which the cloud storage is to be placed (figure 4.8):

![Image of Cloud Storage Configuration Processing With cm-cloud-storage: Network Selection](image2.png)

Figure 4.8: Cloud Storage Configuration Processing With cm-cloud-storage: Network Selection

After having selected the network, a category for the storage nodes is set (figure 4.9):

![Image of Cloud Storage Configuration Processing With cm-cloud-storage: Category Selection](image3.png)

Figure 4.9: Cloud Storage Configuration Processing With cm-cloud-storage: Category Selection

It is recommended that a new category be created (figure 4.10):

![Image of Cloud Storage Configuration Processing With cm-cloud-storage: Category Selection](image4.png)
4.3 Submitting Jobs With cmsub And Cloud Storage Nodes, For Cluster Extension Clusters

The new category will be created by cloning and modifying a base category (see help). Select a base category:

```
default
westeurope-cloud-node
azure-cloud-director
aws-cloud-director
```

A bucket name can be set (figure 4.11):

```
S3 bucket name

config-config-561d553d-3ac2-4433-9e89-be4943c437e5
```

A workload manager is set for the cloud storage (figure 4.12):

```
Workload Manager

lsf
eclipse
 turn  Recommended
torque
 sge
qsub
qsub
```

It is recommended that a new queue be created for jobs that use the storage (figure 4.13):

```
Select workload queue.

[ Create new queue ]  Recommended
```

The queues can be assigned to the cloud category (figure 4.14):

© Bright Computing, Inc.
Figure 4.14: Cloud Storage Configuration Processing With `cm-cloud-storage`: Setting The Queue Category

The summary screen allows the configuration to be saved and to be deployed (figure 4.15):

Figure 4.15: Cloud Storage Configuration Processing With `cm-cloud-storage`: Summary Screen

If the configuration is to be saved, then the file path should be specified (figure 4.16):

Figure 4.16: Cloud Storage Configuration Processing With `cm-cloud-storage`: Save & Deploy Screen

/root/cm-cloud-storage-setup.conf is the suggested default. On exit, the saved configuration can be run with:

Example

[root@bright82 ~]# cm-cloud-storage-setup -c cm-cloud-storage-setup.conf

Configuring `cmsub` Properties With `cmsh`

The storage node policy settings can be modified via CMDaemon using `cmsh`:

[root@bright82 ~]# cmsh
[bright82]# cmsub
[bright82->cmsub[cmsub]][%] storagenodepolicies
[bright82->cmsub[cmsub]->storagenodepolicies][%] list
Name (key) Template for cloud nodes
-----------------------------------------------
us-east-1-policy us-east-1-storage-template
[bright82->cmsub[cmsub]->storagenodepolicies][%] use us-east-1-policy

© Bright Computing, Inc.
### 4.4 Miscellaneous Cloud Commands

#### 4.4.1 The cm-cloud-copy Tool

The cm-cloud-copy tool is automatically installed with the cmdaemon-cmsub package (section 4.3.1). Its purpose is to transfer data to and from AWS storage.

It is used automatically as a backend to cmsub to create and remove AWS storage containers in AWS S3, and to upload and download files and directories to those containers.

The cm-cloud-copy tool can also be used as a standalone tool by the cluster administrator directly, on loading the cm-cloud-copy module. However because its behavior may change due to development, it should only be used if the administrator has explicitly been instructed to do so by Bright Computing engineers. At the time of writing, May 2018, its use requires that the cm-cloud-copy module is loaded. A short help can then be seen on running cm-cloud-copy without options, while more information and examples can be found in the cm-cloud-copy(1) man page.
4.4.2 The cm-manipulate-internal-exclude-lists Tool

The cm-manipulate-internal-exclude-lists tool is not strictly a cloud command, because it can be used outside the cloud.

However it turns out to be useful for defining exclusions for cloud directors and edge directors.

Its usage is:

```
# cm-manipulate-internal-exclude-lists -h
```

Usage: `cm-manipulate-internal-exclude-lists [OPTIONS]`

Options:
- `-n, --node <name>` : hostname or type of node to be manipulated (default CloudNode)
- `-d, --data <file>` : set full exclude to contents of file
- `-p, --path <path>` : fspart path to update (default /cm/shared)
- `-h, --help` : show this help
- `-f, --full` : manipulate full exclude list (default)
- `-s, --sync` : manipulate sync exclude list
- `-u, --update` : manipulate update exclude list
- `-g, --grab` : manipulate grab exclude list
- `-w, --grabnew` : manipulate grabnew exclude list

Warning:

Only use this tool if you know what you're doing!

An example is if /cm/shared is very large. Normally this would be copied over to the cloud director. Often many paths on that directory are not needed, and copying those paths over would waste resources.

In such a case, the command can be used to update the exclude lists for the cloud director so that the data transferred from /cm/shared to the cloud director is restricted. For example, restricting a cloud director `<cloud-director>` using the exclude lists `excludelistfullinstall`, `excludelistsyncinstall`, and `excludelistupdate` (section 5.6 of the Administrator Manual) can be specified with:

Example

```
# cm-manipulate-internal-exclude-lists --full --node <cloud-director> --data <file with the exclude paths>
# cm-manipulate-internal-exclude-lists --sync --node <cloud-director> --data <file with the exclude paths>
# cm-manipulate-internal-exclude-lists --update --node <cloud-director> --data <file with the exclude paths>
```

The format of `<file with the exclude paths>` is an rsync pattern. So if `useless` is a directory with content that is of no use to a cloud director, and the directory is under /cm/shared, then /cm/shared/useless can be excluded by placing a line:

```
- /cm/shared/useless
```

in the file specified for the --data option.
Cluster Extension Cloudbursting With Azure

5.1 Introduction To Cluster Extension Cloudbursting With Azure

Cluster extension cloudbursting with AWS is covered in Chapter 3, where a GUI approach is described, and is also covered in section 4.1, where a text interface approach is described.

Cluster extension cloudbursting with Microsoft Azure is covered in this chapter (Chapter 5). The procedure is somewhat similar to that for AWS:

- The prerequisites to cloudburst into Azure are the same as those of cloudbursting into AWS, and are as previously described on page 25.
  
  In summary, the prerequisites are as follows:
  
  - an activated cluster license should be ensured
  - an Azure account should exist
  - Bright Cluster Manager must be registered as an Azure AD application (page 58)
  - UDP port 1194 should be open

- The techniques to cloudburst into Azure are also the same as that of cloudbursting into AWS, and are as previously described on page 26.
  
  In summary, the techniques are as follows:
  
  - a cloud director is set up in the cloud then started up
  - cloud nodes are then provisioned from the cloud director

- The deployment of cluster extension cloudbursting for Azure is carried out in a similar way to how it is done for AWS.

  In summary, the tools used to deploy cluster extension cloudbursting for Azure are as follows:
  
  - the Ncurses `cm-cluster-extension` utility, run from the command line (section 5.2)
  - the Azure Wizard, run from Bright View.

5.2 Cluster Extension Into Azure

Section 4.1.1 introduces the `cm-cluster-extension` Ncurses wizard, which is run on the head node when configuring a cluster extension for Azure or AWS. After the cluster extension configuration is completed, the cluster is capable of extending into the cloud by having cloud nodes power up into the cloud. This section (section 5.2) covers how `cm-cluster-extension` can be run for Azure, and how clouds nodes can be deployed for Azure.
There is also a Bright View browser-based wizard for cluster extension into Azure. The browser wizard is accessible via the clickpath: Cloud→Azure→Azure Wizard. If the browser wizard is used, then the documentation here (section 5.2) for cm-cluster-extension can be followed since it is a very similar procedure.

**Running The cm-cluster-extension Command Line Options As A Shell Dialog**

The cm-cluster-extension utility can be run as a dialog from the command line environment, as described in the section starting from page 43. Running it as an Ncurses dialog is however easier, and is described next.

**Running The cm-cluster-extension Ncurses Dialog For Cluster Extension Into Azure**

The cm-cluster-extension utility can be run as a more user-friendly Ncurses session within the text environment. In a session described starting from page 45, an AWS cluster extension configuration is generated and deployed. In the session that is now described here, an Azure cluster extension configuration is generated and deployed instead:

As in the AWS case, the cm-cluster-extension script is run without options, to bring up the Ncurses main screen (figure 5.1):

![Figure 5.1: Configuration Processing With cm-cluster-extension: Azure Selection](image)

The Azure option is selected in this session instead of the AWS option. The next screen is then the Azure credentials screen (figure 5.2):

![Figure 5.2: Configuration Processing With cm-cluster-extension: Azure Credentials](image)

The inputs that are required here are Azure credentials, and exist for an activated Azure account which has had Bright Cluster Manager registered as an application.

**How Bright Cluster Manager can be registered as an Azure application:** Registration of an Azure application can be carried out with the Azure portal at https://portal.azure.com. The portal is accessible with an active Azure account. After logging in, navigating to locations via clickpaths described...
next is possible. The steps to ensure a registration are then as follows:

- User settings should first be checked to see if users can register applications. A clickpath to view this is:
  Azure Active Directory → User settings → Users can register applications

- The subscriptions should be checked for permissions. The clickpath to view subscriptions is simply:
  Subscriptions

  Within the subscription display the role can be viewed to determine if the account has adequate permissions to assign an AD application to a role. The account must have Microsoft.Authorization/*/Write access to assign an Azure AD application to a role. Assigning the Contributor role allows this access. Role-based access control (RBAC) is discussed at https://docs.microsoft.com/en-us/azure/active-directory/role-based-access-control-manage-access-rest

- The user, for example, `<fred>`, should be checked for permissions. A suitable clickpath would be:
  Azure Active Directory → Users and groups → `<fred>` → Azure resources

  The Azure resources for the user, who is assigned the subscription, should show the role and assignment value. Suitable settings would be:

  ROLE: Contributor
  ASSIGNED TO: `<fred>`

- Network, Compute, and Storage namespaces must be registered.

  A convenient way to check that this is the case, is to use the Azure CLI tool from the head node. Instructions for installing it are available at https://docs.microsoft.com/en-us/cli/azure/install-azure-cli.

  After installation, a list of namespaces can be seen by running:

  `az provider list --query "[].{Provider:namespace, Status:registrationState}" --out table`

  If the tool is run for the first time, then the tool gives the user a code and a URL. Using these, the user can authenticate the head node via a web browser.

  The required namespaces can be registered, if needed, with:

  `az provider register --namespace Microsoft.Network --wait`
  `az provider register --namespace Microsoft.Compute --wait`
  `az provider register --namespace Microsoft.Storage --wait`
  `az provider register --namespace Microsoft.ADHybridHealthService --wait`
  `az provider register --namespace Microsoft.Authorization --wait`
  `az provider register --namespace Microsoft.Billing --wait`
  `az provider register --namespace Microsoft.ClassicSubscription --wait`
  `az provider register --namespace Microsoft.Commerce --wait`
  `az provider register --namespace Microsoft.Consumption --wait`
  `az provider register --namespace Microsoft.Features --wait`
  `az provider register --namespace Microsoft.MarketplaceOrdering --wait`
  `az provider register --namespace Microsoft.Resources --wait`
  `az provider register --namespace Microsoft.support --wait`
Create Azure Active Directory application:

With all the permissions in place, the application can now be registered via the clickpath: Azure Active Directory → App registrations

The application name and application URL values can be arbitrary since they are not actually used by cm-cluster-extension. The application type should be set to: Web app / API

The Client ID and Client Secret values are only available to Azure admin users, or the Azure application owners. Regular users cannot obtain these values.

If the security settings allow Azure users to define their own Azure applications, then they can in theory create their own Azure application under the subscription, and use the data for that Azure application to get a Client ID and Client Secret.

The credentials can now be picked up from the Azure portal account via the clickpaths shown in the following table:

<table>
<thead>
<tr>
<th>Ncurses</th>
<th>Clickpath From Azure Portal Menu After Azure Portal Login</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subscription ID</td>
<td>Subscriptions → SUBSCRIPTION ID</td>
</tr>
<tr>
<td>Tenant ID</td>
<td>Azure Active Directory → Properties → Directory ID</td>
</tr>
<tr>
<td>Client ID</td>
<td>Azure Active Directory → App registrations → APPLICATION ID</td>
</tr>
<tr>
<td>Client Secret</td>
<td>Azure Active Directory → App registrations → APPLICATION ID → Keys → [the generated key must be noted]</td>
</tr>
</tbody>
</table>

*After filling in the DESCRIPTION and EXPIRES fields at the end of this clickpath, and saving the values, the key is generated, and displayed once. The key must be noted down by the user because it cannot be retrieved.

The Provider Name in figure 5.2 can be set to any user-defined value. For Azure, a sensible, if unimaginative value, is simply azure.

After the credentials have been accepted, then Azure regions can be selected (figure 5.3):

```
Please select the region(s) to which you would like to extend your cluster to.

The setup process will later create and configure a VPE for each selected region.

You can always add and configure additional regions later on.

<table>
<thead>
<tr>
<th>[ ] westus2</th>
<th>[ ] southcentralus</th>
<th>[ ] westus</th>
<th>[ ] australiaeast</th>
<th>[ ] southindia</th>
<th>[ ] eastus</th>
<th>[ ] westus</th>
<th>[ ] australiaeast</th>
<th>[ ] eastus</th>
<th>[ ] westus</th>
<th>[ ] southcentralus</th>
<th>[ ] westus</th>
<th>[ ] australiaeast</th>
<th>[ ] southindia</th>
<th>[ ] eastus</th>
<th>[ ] westus</th>
</tr>
</thead>
</table>
```

Figure 5.3: Configuration Processing With cm-cluster-extension: Azure Regions

Azure regions are regional data centers, and the cloud director for a region helps manage the regular cloud nodes in that region when the cluster is extended into there.

The default instance type for the regular cloud nodes is then set (figure 5.4):

© Bright Computing, Inc.
A default Azure virtual machine type that works well for general cloud node purposes is the D1_v2 type. There are many possible machine types, and they are documented online at https://docs.microsoft.com/en-us/azure/virtual-machines/windows/sizes. A summary listing of the supported types can be viewed in cmsh with:

[root@b80 ~]# cmsh -c "cloud use azure ; types ; list"

or via the Bright View clickpath:

Cloud→Azure→Azure VM Sizes

The default instance type for the cloud directors is then set (figure 5.5):

The same default size of the D1_v2 type that works for regular cloud nodes is typically adequate for cloud director nodes too, for small clusters.

The summary screen (figure 5.6) allows the administrator to look over the configuration before deployment:
As in the AWS summary screen, the Azure summary screen allows the following:

- An administrator can just go ahead, save the configuration, and deploy the cluster extension. This is usually the expected action.
- The configuration settings YAML file can be viewed. To scroll, the PageUp and PageDown keys are used.
- An advanced configuration settings screen can be accessed in addition to the standard settings. The advanced settings are usually left alone.
- The configuration file, `<configuration file>`, is `cm-cluster-extension.conf` by default. The file can be saved, by default to the home directory of the user. On exiting the Ncurses dialog, deployment with that configuration can be carried out manually by running:

```bash
cm-cluster-extension -c <configuration file>
```

**Deployment Of An Azure Configuration Created With cm-cluster-extension**

During configuration deployment, as the configuration is processed, text output indicates the progress. At the end of processing, the message

```
Azure Cloud extension configuration finished
```

indicates that the cluster has been extended successfully.

No nodes are activated yet within Azure. To start them up, the components of the cluster extension service for Azure must be started up by

- powering up the cloud directors, as introduced for AWS in section 3.2. The procedure for Azure is similar.
- powering on the cloud nodes after the cloud directors are up. This may require first creating new cloud nodes, as introduced for AWS in section 3.3. The procedure for Azure is similar.

When powering up, the cloud director can be installed from scratch (section 3.2), or from a snapshot. For example, running the `power on` command from the device mode of `cmsh` on a head node shows amongst others the following states (some output elided or ellipsized):

**Example**

```bash
[b80->device]% power on westeurope-director
cloud ......................... [  ON  ] westeurope-director
... [notice] b80: westeurope-director [ PENDING ] (Instance has started)
... [notice] b80: New certificate request with ID: 9
... [notice] b80: westeurope-director [ INSTALLING ] (node installer started)
```

© Bright Computing, Inc.
5.2 Cluster Extension Into Azure

... [notice] b80: New certificate request with ID: 10 (ldaps)
... [notice] b80: westeurope-director [ INSTALLER_CALLINGINIT ] (switching to local root)
...
... [notice] b80: westeurope-director [ UP ]

Example
[root@bright82 ~]# ps uww -C rsync | grep -o ' /cm/.*$'
/cm/shared/ syncer@172.21.255.251::target//cm/shared/

Tracking Cloud Director Startup From cmsh
The provisioningstatus command in the softwareimage mode of cmsh can be used to view the provisioning status (some output elided):

Example
[root@bright82 ~]# cmsh -c "softwareimage provisioningstatus"
...
+ westeurope-director
...
Up to date images: none
Out of date images: default-image

In the preceding output, the absence of an entry for “Up to date images” shows that the cloud director does not yet have an image that it can provision to the cloud nodes. After some time, the last few lines of output should change to something like:

Example
+ westeurope-director
...
Up to date images: default-image

This indicates the image for the cloud nodes is now ready.

With the -a option, the provisioningstatus -a command gives details that may be helpful. For example, while the cloud director is having the default software image placed on it for provisioning purposes, the source and destination paths are /cm/images/default-image:

Example
[root@bright82 ~]# cmsh -c "softwareimage provisioningstatus -a"
Request ID(s): 4
Source node: bright82
Source path: /cm/images/default-image
Destination node: westeurope-director
Destination path: /cm/images/default-image
...

After some time, when the shared filesystem is being provisioned, then an indication of progress is shown by the Request ID incrementing, and the source and destination paths changing to the /cm/shared directory:

Example
[root@bright82 ~]# cmsh -c "softwareimage provisioningstatus -a"
Request ID(s): 5
Source node: bright82
Source path: /cm/shared
Destination node: westeurope-director
Destination path: /cm/shared
...

© Bright Computing, Inc.
After the shared directory and the cloud node software images are provisioned, the cloud director is fully up. Cloud node instances can then be powered up and provisioned from the cloud director. The instances can be started up from scratch (section 3.2), or from snapshot (section 3.4).

### 5.3 Cluster Extension Into Azure: Cloud Node Startup From Scratch

This section discusses the configuration of regular cloud node startup from scratch.\(^1\)

To configure regular cloud nodes in Azure from scratch does not require a working cloud director. However to boot up the regular cloud nodes does require that the cloud director be up, and that the associated networks to the regular cloud nodes and to the head node be configured correctly.

If needed, additional cloud provisioning nodes (section 5.2 of the Administrator Manual) can be configured by assigning the provisioning role to cloud nodes, along with appropriate nodegroups (page 153 of the Administrator Manual) values, in order to create a provisioning hierarchy.

Similarly to how it is done in AWS, the creation and configuration of regular cloud node objects in Azure is conveniently carried out by cloning another regular cloud node, from one of the default cloud nodes already created by the cluster extension wizard (section 5.2). A clickpath to do this cloning in Bright View is:

```
Cloud→Cloud Nodes→<cloud node hostname>→↓Clone
```

Cloud node objects can also be created in cmsh as described in section 4.2.

### 5.4 Cluster Extension Into Azure: shutdown Vs power off

An Azure cloud node has two stopped states:

1. **stopped**: A node running within Azure can be set to this state by running the `shutdown` command:
   - within the device mode of cmsh
   - with Bright View, using the clickpath:
     ```
     Cloud→Cloud Nodes→<cloud node hostname>→↓OS→Shutdown
     ```
   - Or by clicking the stop button for that node within the Azure web portal, once.

2. **stopped (deallocated)**: A node running within Azure can be set to this state by running the `power off` command:
   - within the device mode of cmsh
   - with Bright View, using the clickpath:
     ```
     Cloud→Cloud Nodes→<cloud node hostname>→↓Power→Off
     ```
   - Or by clicking on the stop button within the Azure web portal, twice.

Carrying out a `power off` command is like a hard power off command, which can under some unusual conditions cause filesystem corruption. It is therefore safer to run the `shutdown` command first, wait for the node to shut down via the OS. After that, running the `power off` command ensures that the node is deallocated.

From a financial point of view when using Azure, a node that is shut down but not deallocated continues to incur costs. However, a node that is deallocated does not continue to incur costs.

---

\(^1\)The configuration of cloud director and node startup from snapshot is also possible. How to do this for AWS is discussed in section 3.4. Doing this for Azure is rather more complicated and confusing. At the time of writing (August 2017), configuring this is therefore planned as a wizard-assisted option for a future version of Bright Cluster Manager, with a priority that depends on the level of interest for this feature from customers.
5.5 Submitting Jobs With \texttt{cmsub} And Cloud Storage Nodes, For Azure Cluster Extension Clusters

The \texttt{cmsub} utility, a job submission wrapper for end users for cluster extension clusters, is introduced and documented for AWS cluster extension in section 4.3. As a summary, its configuration procedure consists of:

- Making sure the \texttt{cmdaemon-cmsub} package is installed on the head node and the cloud image
- Ensuring the users that are to use \texttt{cmsub} have the \texttt{cloudjob} profile
- Making sure that cloud storage nodes are set up. The administrator can run \texttt{cm-cloud-storage-setup} to configure the cloud storage nodes.

The details of the configuration procedure for \texttt{cmsub} for Azure cluster extension is almost identical to that for AWS. The configuration procedure documented in section 4.3 can therefore also be followed for Azure.

How the end user can use \texttt{cmsub} is documented in section 4.7 of the \textit{User Manual}.

Cloud Considerations And Choices With Bright Cluster Manager

6.1 Differences Between Cluster On Demand And Cluster Extension

Some explicit differences between Cluster On Demand and Cluster Extension clusters are:

<table>
<thead>
<tr>
<th>Cluster On Demand</th>
<th>Cluster Extension</th>
</tr>
</thead>
<tbody>
<tr>
<td>cloud nodes only in 1 region</td>
<td>cloud nodes can use many regions</td>
</tr>
<tr>
<td>no cloud director</td>
<td>uses one or more cloud directors per region</td>
</tr>
<tr>
<td>no failover head node</td>
<td>failover head node possible</td>
</tr>
<tr>
<td>no VPN or NetMap</td>
<td>VPN and NetMap</td>
</tr>
<tr>
<td>no externalnet interface on head</td>
<td>can have an external interface</td>
</tr>
<tr>
<td>cluster has publicly accessible IP address</td>
<td>cloud directors have publicly accessible IP addresses</td>
</tr>
</tbody>
</table>

A note about the last entry: The access to the cloud director addresses can be restricted to an administrator-defined set of IP addresses, using the “Externally visible IP” entry in figure 3.1 of the Administrator Manual.

6.2 Hardware And Software Availability

Bright Computing head node AMIs are available for the following distributions: RHEL6/7, SL6/SL7, CentOS6/CentOS7, and SLES 12.

AMIs with GPU computing instances are available with Amazon cloud computing services, and can be used with Bright Computing AMIs with hvm in the name (not xen in the name).

To power the system off, a `shutdown -h now` can be used, or the power commands for Bright View or `cmsh` can be executed. These commands stop the instance, without terminating it. Any associated extra drives that were created need to be removed manually, via the Volumes screen in the Elastic Block Store resource item in the navigation menu of the AWS Management Console.

6.3 Reducing Running Costs

© Bright Computing, Inc.
6.3.1 Spot Pricing

The spot price field is a mechanism to take advantage of cheaper pricing made available at irregular times. The mechanism allows the user to decide a threshold spot price (a price quote) in US dollars per hour for instances. Instances that run while under the threshold are called spot instances. Spot instances are described further at http://aws.amazon.com/ec2/spot-instances/.

With the pricing threshold set:

- If the set spot price threshold is above the instantaneous spot price, then the spot instances run.
- If the set spot price threshold is below the instantaneous spot price, then the spot instances are killed.
- If the set spot price threshold is $/h, then no conditions apply, and the instances will run on demand regardless of the instantaneous spot price.

An on demand instance is one that runs regardless of the price, according to the pricing at http://aws.amazon.com/ec2/pricing/.

A persistent request is one that will retry running a spot instance if the conditions allow it.

6.3.2 Storage Space Reduction

Reducing the amount of EBS disk storage used per cloud node or per cloud director is often feasible. 15 GB is usually enough for a cloud director, and 5 GB is usually enough for a cloud node with common requirements. In cmsh these values can be set with:

Example

[bright82]% device cloudsettings eu-west-1-director
[bright82->device[eu-west-1-director]->cloudsettings]% storage
[bright82->...->cloudsettings->storage]% set ebs size 15GB; commit
[bright82->...->cloudsettings->storage]% device cloudsettings cnode001
[bright82->device[cnode001]->cloudsettings]% storage
[bright82->...->cloudsettings->storage]% set ebs size 5GB; commit

The value for the cloud node EBS storage can also be set via Bright View, using the clickpath:

Cloud→Cloud Nodes→Edit→Cloud settings→Storage→ebs→Edit→size

6.4 Address Resolution In Cluster Extension Networks

6.4.1 Resolution And globalnet

The globalnet network is introduced in section 3.2.3 of the Administrator Manual. It allows an extra level of redirection during node resolution. The reason for the redirection is that it allows the resolution of node names across the entire cluster in a hybrid cluster, regardless of whether the node is a cloud node (cloud director node or regular cloud node) or a non-cloud node (head node, regular node or networked device). A special way of resolving nodes is needed because the Amazon IP addresses are in the 10.0.0.0/8 network space, which conflicts with some of the address spaces used by Bright Cluster Manager.

There are no IP addresses defined by globalnet itself. Instead, a node, with its domain defined by the globalnet network parameters, has its name resolved by another network to an IP address. The resolution is done by the nameserver on the head node for all nodes.

---

1irregular turns out to be random within a tight range, bound to a reserve price. Or rather, that was the case during the period 20th January–13th July, 2010 that was analyzed by Ben-Yehuda et al, http://www.cs.technion.ac.il/users/wwwb/cgi-bin/tr-info.cgi/2011/CS/CS-2011-09
6.4.2 Resolution In And Out Of The Cloud

The networks, their addresses, their types, and their domains can be listed from the network node in cmsh:

```
[bright73->network] % list -f name:26,type:12,netmaskbits:8,baseaddress:13,domainname:24
name (key) type netmask baseaddress domainname
-------------------------- ------------ -------- ------------- ------------------------
us-east-1 Tunnel 16 172.21.0.0
externalnet External 24 192.168.100.0 brightcomputing.com
globalnet Global 0 0.0.0.0 cm.cluster
internalnet Internal 16 10.141.0.0 eth.cluster
netmap NetMap 16 172.30.0.0
vpc-eu-central-1-private Cloud (VPC) 17 10.42.128.0 vpc-eu-central-1.cluster
vpc-eu-central-1-public Cloud (VPC) 24 10.42.0.0 vpc-eu-central-1.cluster
```

In a Type 1 network (section 3.3.7 of the Installation Manual), the head node is connected to internalnet. When a cloud service is configured, the head node is also “connected” to the CMDaemon-managed NetMap “network”. It is useful to think of NetMap as a special network, although it is actually a network mapping from the cloud to internalnet. That is, it connects (maps) from the nodes in one or more cloud networks such as the us-east-1 network provided by Amazon, to IP addresses provided by netmap. The mapping is set up when a cloud extension is set up. With this mapping, packets using NetMap go from the cloud, via an OpenVPN connection to the NetMap IP address. Once the packets reach the OpenVPN interface for that address, which is actually on the head node, they are forwarded via Shorewall’s IPTables rules to their destination nodes on internalnet.

With default settings, nodes on the network internalnet and nodes in a cloud network such as us-east-1 are both resolved with the help of the cm.cluster domain defined in globalnet. For a cluster with default settings and using the cloud network us-east-1, the resolution of the IP address of 1. a regular node and 2. a regular cloud node, takes place as follows:

1. node001, a regular node in the internalnet network, is resolved for node001.cm.cluster to
   (a) 10.141.0.1, when at the head node. The cluster manager assigns this address, which is on internalnet. It could also be an ibnet address instead, such as 10.149.0.1, if InfiniBand has been configured for the nodes instead of Ethernet.
   (b) 172.30.0.1 when at the cloud director or regular cloud node. The cluster manager assigns this address, which is a NetMap address. It helps route from the cloud to a regular node. It is not actually an IP address on the interface of the regular node, but it is convenient to think of it as being the IP address of the regular node.

2. cnode001, a regular cloud node in the us-east-1 network, is resolved for cnode001.cm.cluster to:
   (a) 172.21.0.1 when at the head node. The cluster manager assigns this address, which is an OpenVPN tunnel address on us-east-1.
   (b) an IP address within 10.0.0.0/8 (10.0.0.1–10.255.255.254) when at a regular cloud node or at a cloud director. The Amazon cloud network service assigns the addresses in this network to the cloud director and regular cloud nodes after it notices the regular cloud node interface is up.

An explanation of the networks mentioned in the preceding list follows:

- The nodes within all available cloud networks (all networks such as for example, us-east-1, us-west-1, and so on) are given CMDaemon-assigned addresses in the cloud node space range 172.16.0.0–172.29.255.255. In CIDR notation that is: 172.16.0.0/12 (172.16.0.0–172.31.255.255), except for 172.31.0.0/15 (172.30.0.0–172.31.255.255).
The network address space 172.30.0.0/16 (172.30.0.0–172.30.255.255) is taken by the CMDaemon-assigned NetMap network, explained shortly.

Each node in a cloud network is also assigned an address in the network addressing space provided by Amazon VPC networking. The assignment of IP addresses to nodes within the 10.0.0.0/8 range is decided by Amazon via DHCP. The VPC networks for regular cloud nodes and cloud director nodes are subnets in this range.

The **netmap** “network” (figure 6.1) is a helper mapping reserved for use in routing from the cloud (that is, from a cloud director or a cloud node) to a regular node. The mapping uses the 172.30.0.0/16 addressing scheme. Its routing is asymmetrical, that is, a NetMap mapping from a regular node to the cloud does not exist. Packets from a regular node to the cloud do however resolve to the cloud network as indicated by 2(a) in the preceding.

As pointed out in the introduction to this section (6.4), the main reason for the IP addressing network scheme used is to avoid IP address conflicts between nodes within the cloud and nodes outside the cloud.

The **difference** in resolution of the IP address for the nodes as listed in points 1 and 2 in the preceding text is primarily to get the lowest overhead route between the source and destination of the packet being routed. Thus, for example, a packet gets from the regular cloud node to the cloud director with less overhead if using the Amazon cloud IP addressing scheme (10.0.0.0/8) than if using the Bright OpenVPN addressing scheme (172.21.0.0/16). A secondary reason is convenience and reduction of networking complexity. For example, a node in the cloud may shut down and start up, and get an arbitrary Amazon IP address, but using an OpenVPN network such as us-east-1 allows it to retain its OpenVPN address and thus stay identified instead of having the properties that have been assigned to it under Bright Cluster Manager become useless.

### 6.5 Internet Connectivity For Cloud Nodes

If a cloudbursting setup is connected to the internet with the default settings, then only the CX-OS cloud compute nodes have no access to the internet.
Cloud compute node types in the other cloudbursting setups—CX-AWS, CX-Azure, COD-AWS, COD-Azure, and COD-OS—can all access the internet by default. This is elaborated upon in Table 6.5:

<table>
<thead>
<tr>
<th>Cloud node type</th>
<th>Internet access by default?</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>CX-AWS</td>
<td>Yes</td>
<td>Cloud compute nodes are routed via an sNAT gateway cloud director node. They therefore do not normally require assignment of Elastic IPs. If assigning an Elastic IP to a node is required, then such a node should be created on the ‘public’ VPC subnet (by default cloud compute nodes are created on the ‘private’ VPC subnet).</td>
</tr>
<tr>
<td>CX-Azure</td>
<td>Yes</td>
<td>Cloud compute nodes use the built-in NAT capabilities of Azure’s gateway when accessing the internet.</td>
</tr>
<tr>
<td>CX-OS</td>
<td>No</td>
<td>Cloud compute nodes are routed via a cloud director sNAT gateway. However for this to work in a OpenStack environment, the port security plugin needs to be enabled for Neutron, followed by disabling the port security setting on the cloud director ports (section 7.4 of the OpenStack Deployment Manual). By default, the port security plugin is disabled for Neutron, while the port security setting is in an enabled state. Disabling the security setting causes the security groups to be no longer applied in the cloud director. This means anyone with Layer-3 (IP) access to the cloud director could try to establish a connection to any of the cloud director’s ports. Therefore, by default for CX-OS, the port security plugin is left disabled, and the port security setting left enabled.</td>
</tr>
<tr>
<td>COD-AWS</td>
<td>Yes</td>
<td>Cloud compute nodes use the head node as an sNAT gateway. If the head node is overloaded with network traffic, then an AWS NAT gateway can be added to the VPC, and configure that device to be the default gateway for a private subnet by modifying the routing table of that subnet.</td>
</tr>
<tr>
<td>COD-Azure</td>
<td>Yes</td>
<td>Cloud compute nodes can access the internet via TCP/UDP using the Azure Load Balancer. ICMP packets are silently discarded. ICMP traffic can only be allowed by associating a public IP address to the compute node. Microsoft advises its users to use an alternative to ping for connectivity testing that works using TCP packets, and tries to connect to a specific port.</td>
</tr>
<tr>
<td>COD-OS</td>
<td>Yes</td>
<td>Cloud compute nodes are routed via an sNAT gateway head node.</td>
</tr>
</tbody>
</table>

6.6 Passing Kernel Parameters To Cloud Nodes

If a cluster administrator configures a non-cloud cluster, then kernel parameters can be set for a particular software image used by the regular nodes. For example, in cmsh, if a software image `<image name>`
is used, then kernel parameters such as `root=/dev/sda2 rootdelay=10 pti=auto` can be set via the navigation path:

```
cmsh→softwareimage→use <image name>→set kernelparams "root=/dev/sda2 rootdelay=10 pti=auto"
```

However, kernel parameters are not passed to cloud nodes via this mechanism at the time of writing (November 2019). If there is a need to pass kernel parameters to cloud nodes, then Bright Computing support should be contacted.
Legacy/Current Cloud Instances, And Their Network Addressing Allocations

A virtual private cloud is an implementation of a cluster on a virtual network in a cloud service provider. The Amazon Virtual Private Cloud (Amazon VPC) is an implementation of such a virtual private cloud. The Amazon VPC is documented at http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/using-vpc.html.

Bright Cluster Manager manages VPCs so that the administrator can focus on using them productively, instead of on working out VPC configurations. However, some background on how the integration is done may be useful for administrators that have special requirements, or who are migrating from a legacy Amazon cloud.

The following VPC-related terms are explained and compared in this chapter:

- EC2-Classic (page 73)
- EC2-VPC (page 74)
- classic cloud (page 74)
- default VPC (page 74)
- private cloud (page 74)
- custom VPC (page 74)
- elastic IP addresses (page 77)

7.1 EC2-Classic And EC2-VPC

7.1.1 EC2-Classic Vs EC2-VPC Overview

So far, this manual has discussed configuring clusters within Amazon EC2. The EC2 designation actually covers two kinds of platforms:

- EC2-Classic: This is no longer supported by Bright Cluster Manager from version 7.3 onwards. It provides an environment that corresponds to a physical network. Instances in the same region exist on the same physical network and rely on explicitly configured security groups to restrict unauthorized access from other instances on the same network. A cloud instance that is created in such a network can be called a classic cloud cluster, or simply a classic cloud.

Amazon is gradually phasing out the EC2-Classic platform.
• EC2-VPC: This platform is replacing EC2-Classic. It provides an environment corresponding to an isolated virtual network. A cloud cluster instance implemented on this virtual network is thus a virtual private cloud, or VPC, as described at the start of this chapter (Chapter 7).

The EC2-VPC platform offers some extra features that are not available, or not as easy to configure, on the EC2-Classic platform:

- Multiple VPCs can be configured per region
- The inherent isolation of Amazon VPCs makes them more secure by default
- Their network properties can be customized

The isolated network design of a VPC means that instances started within a VPC cannot by default communicate with instances outside. Elastic IP addresses (page 77) are used to explicitly allow communication with the outside.

7.1.2 EC2-Classic Vs EC2-VPC And AWS Account Creation Date

The type of platform that can be accessed by an AWS account varies as indicated by the following table:

<table>
<thead>
<tr>
<th>Account Creation Date</th>
<th>Typical Platform Offered</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before start of 2013</td>
<td>EC2-Classic only</td>
</tr>
<tr>
<td>In first half of 2013</td>
<td>EC2-Classic or EC2-VPC*</td>
</tr>
<tr>
<td>After first half of 2013</td>
<td>EC2-VPC only, in most or all regions</td>
</tr>
</tbody>
</table>

*Typically depends on the region accessed.

AWS accounts created after 4th December 2013 do not provide an EC2-Classic platform. However, to maintain backward compatibility for users who are migrating to EC2-VPC, and who have applications that run on the EC2-Classic platform, Amazon provides the defaultVPC instance on the EC2-VPC platform.

7.1.3 The Classic Cloud And The DefaultVPC Instances

The classic cloud is a cloud instance that EC2-Classic supports. This is not supported by Bright Cluster Manager from version 7.3 onwards.

The defaultVPC instance is a special VPC instance that emulates EC2-Classic behavior on the EC2-VPC platform. This allows legacy applications that do not support EC2-VPC to run on it. A legacy application that runs in a defaultVPC instance may be thought of as having its EC2-Classic API calls translated into EC2-VPC API calls. The defaultVPC instance is available in all regions that do not offer the EC2-Classic platform, but it is not supported by Bright Cluster Manager.

7.1.4 The Private Cloud And Custom VPC Instances

A private cloud (without the “virtual” in front) is the term used in the Bright Cluster Manager manuals, as well as by Amazon, and in general, for a general VPC instance.

A custom VPC is the term used in the manual to mean a general VPC instance, but one that is not a defaultVPC instance.

Thus, in terms of math sets:

\[\text{private clouds} = \text{custom VPCs} + \text{defaultVPCs}\]

In the context of Amazon VPCs, the term private cloud is often used by administrators, by convention and for convenience, to mean the more precise term of custom VPC as defined here, implicitly ignoring possible defaultVPC instances. The Bright Cluster Manager software itself also follows this convention, which is almost invariably true for Amazon VPCs nowadays, and an absolute truth as far as Bright Cluster Manager from version 7.3 onwards is concerned. So, as far as Bright Cluster Manager 7.3 onwards is concerned:

\[\text{private clouds} = \text{custom VPCs}\]
7.1.5 Cloud Cluster Terminology Summary

The cluster terminology used so far can be summarized as follows:

<table>
<thead>
<tr>
<th>cluster term</th>
<th>platform</th>
<th>type and connectivity</th>
</tr>
</thead>
<tbody>
<tr>
<td>classic cloud</td>
<td>EC2-Classic</td>
<td>classic cloud cluster that has direct connectivity to the outside</td>
</tr>
<tr>
<td>defaultVPC</td>
<td>EC2-VPC</td>
<td>a VPC that looks like it has direct connectivity to the outside because it emulates a classic cloud cluster</td>
</tr>
<tr>
<td>custom VPC</td>
<td>EC2-VPC</td>
<td>isolated VPC with no connectivity to the outside by default, and NAT gateway connectivity to the outside when made to connect</td>
</tr>
<tr>
<td>private cloud</td>
<td>EC2-VPC</td>
<td>both defaultVPC and custom VPC</td>
</tr>
</tbody>
</table>

7.2 Comparison Of EC2-Classic And EC2-VPC Platforms

There are several differences between EC2-Classic and EC2-VPC platforms. The most important ones are:

- Cloud nodes created inside the EC2-VPC platform do not have an external (public) IP address assigned to them by default. An exception to this is the case of nodes running in a defaultVPC instance, which emulates EC2-Classic network behaviour. Having no public IP address by default allows for a greater degree of out-of-the-box security.

- Custom VPCs are self-contained and securely isolated from the instance of other users.

- Custom VPCs are partitioned into multiple network segments, called subnets (section 7.3.1).

- It is possible to specify a custom base network address for the custom VPC. This is in contrast to the EC2-Classic platform, where a base network address always has the value of 10.0.0.0/8. For a defaultVPC instance the base network address takes the value of 172.30.0.0/16.

7.3 Setting Up And Creating A Custom VPC

From Bright Cluster Manager version 7.3 onwards, the EC2-classic platform is no longer available, and all nodes within the cloud provider always run within an EC2-VPC platform.

Custom VPC for Bright Cluster Manager 8.2 subnet allocation, and allocation of EIPs (External IPs) is described in sections 7.3.1–7.3.4.

7.3.1 Subnets In A Custom VPC

The components of a custom VPC include subnets, the nodes that run in them, and static IP addresses. The subnets are logical network segments within the network range of that custom VPC. Subnets can be thought of as interconnected with a central “magic” router, with Bright Cluster Manager managing the routing tables on that router. The routing ensures correct subnet communication. Inside Bright Cluster Manager, subnets are represented as a type of network (section 3.2 of the Administrator Manual), with a value for type set in cmsh to Cloud (VPC), or in Bright View set to CLOUD.

Subnets for a custom VPC must have non-overlapping ranges. If there are multiple custom VPCs being managed by Bright Cluster Manager, then a particular subnet may be assigned to one custom VPC at the most.

Two series of valid network ranges could be:

Example

1. 10.0.0.0-10.0.31.255 (10.0.0.0/19),

© Bright Computing, Inc.
10.0.32.0-10.0.63.255 (10.0.32.0/19),
10.0.64.0-10.0.95.255 (10.0.64.0/19).

2. 192.168.0.0-192.168.0.255 (192.168.0.0/24),

The *sipcalc* command (page 63 of the *Administrator Manual*) is a useful tool for calculating appropriate subnet ranges. At least one subnet must be assigned to a custom VPC before an instance can be created in that cloud. Typically two or more subnets are assigned, as shown in the custom VPC creation example in the following section.

### 7.3.2 Creating The Custom VPC

After subnets have been configured, a custom VPC can be created by specifying:

- the name
- the default region
- base address
- number of netmask bits

The network of the custom VPC must obviously be a superset of its subnets. Any subnets of the custom VPC must also be specified. Subnets can be added to or removed from an already-created custom VPC, but only if any cloud node instances within them are terminated first.

There are several ways to set up and create the subnets and custom VPC instance in Bright Cluster Manager:

1. by using the command line *cm-cluster-extension* utility (section 4.1),
2. by using the Bright View private cloud creation wizard (section 3.1),
3. by manually creating and configuring the *private cloud* object using *cmsh*.

Option 3 is tedious, but does show to the reader some of what the *cm-cluster-extension* utility and cloud creation wizard do. To create and configure a private cloud as in option 3, the following example sessions show how a private cloud can be built with *cmsh*. In the sessions, the subnets to be used for the custom VPC are created first, before creating the private cloud:

- **Subnet creation and cloning:** In the following example session, an arbitrary naming scheme is used for subnets, with a pattern of: `<name of custom VPC>-sn-<number>`. Here, *sn* is an arbitrary abbreviation for “subnet”:

  **Example**

  
  ```bash
  [bright82->network]% add vpc-0-sn-0
  [bright82->network*[vpc-0-sn-0*]]% set type cloud
  [bright82->network*[vpc-0-sn-0*]]% set baseaddress 10.0.0.0
  [bright82->network*[vpc-0-sn-0*]]% set netmaskbits 24
  [bright82->network*[vpc-0-sn-0*]]% set ec2availabilityzone eu-west-1a
  [bright82->network*[vpc-0-sn-0*]]% commit
  ```

  Setting the *ec2availabilityzone* property is optional. It causes the subnet to be created in a specific availability zone. Leaving its value empty creates the subnet inside a randomly chosen availability zone. Having all subnets of the custom VPC inside the same availability zone is advised for better network performance. The availability zone set for the network must be one of the availability zones available for the region inside which the private cloud will be created.

  Once the first subnet has been created, it can be cloned:
7.3 Setting Up And Creating A Custom VPC

Example

[bright82->network]% clone vpc-0-sn-0 vpc-0-sn-1
[bright82->network*[vpc-0-sn-1*]]% set baseaddress 10.0.1.0
[bright82->network*[vpc-0-sn-1*]]% commit

Custom VPC creation: The following example session in the vpc submode of the cloud mode, creates a private cloud called vpc-0. The private cloud is actually a custom VPC according to the strict definition of a private cloud instance in the section on page 74. It is of type ec2 and within a network that contains the two subnets specified earlier.

Example

[bright82->cloud[Amazon EC2]->vpcs]%
[bright82->...->vpcs]% add vpc-0
[bright82->...->vpcs*[vpc-0*]]% set region eu-west-1
[bright82->...*[vpc-0*]]% set baseaddress 10.10.0.0
[bright82->...*[vpc-0*]]% set netmaskbits 16
[bright82->...*[vpc-0*]]% set subnets vpc-0-sn-0 vpc-0-sn-1
[bright82->...*[vpc-0*]]% commit

7.3.3 Elastic IP Addresses And Their Use In Configuring Static IP Addresses

Unlike the deprecated defaultVPC and EC2-Classic instances, a custom VPC instance does not have an externally visible (public) IP address assigned to it by Amazon by default. Without an externally visible IP address, the custom VPC cannot communicate with the internet, and it cannot even be an endpoint to an outside connection. To solve this issue, Amazon elastic IP addresses (EIPs) can be used to assign a public IP address to a custom VPC.

EIP addresses are the public IP addresses that Amazon provides for the AWS account. These addresses are associated with defaultVPC and EC2-Classic cloud instances by Amazon by default. These addresses can also be associated with custom VPC instances. The public addresses in the set of addresses can then be used to expose the custom VPC instance. In this manual and in Bright Cluster Manager, EIPs are referred to as “static IPs” in the cloud context. When allocating a static IP address, the exact IP address that is allocated is a random IP address from the pool of all public IP addresses made available in the specified region by the configured cloud provider.

Automatic allocation of static IP addresses:
When a cloud director instance is started inside a custom VPC, CMDaemon automatically allocates and assigns a static IP address to it. By default, the static IP address is automatically released when the cloud director instance is terminated. This behavior can be changed in the CMDaemon cloud settings for the cloud director.

Manual allocation of static IP addresses:
It is also possible to manually allocate a static IP address to a cloud director using Bright View or cmsh, when the administrator decides to set it.

Allocating a static IP address in cmsh is done using the staticip allocate command, followed by the string indicating the region in which the static IP address is to be allocated. In cmsh, the command is issued inside a cloud provider object. A new static IP address is then made available and can be assigned to instances running within custom VPCs.

After allocation, the static IP address can be assigned and reassigned to any instance inside any custom VPC created within the region in which the IP address was allocated.

Example
Legacy/Current Cloud Instances, And Their Network Addressing Allocations

```
[bright82] cloud use amazonec2
[bright82->cloud[Amazon EC2]]% staticip allocate us-west-1
Allocating Static IP. Please wait...
Successfully allocated the following static IP: 54.215.158.42
[bright82->cloud[Amazon EC2]]% staticip list
Cloud Provider       Cloud Region  Static IP     Assigned to
--------------------- --------------- -------------- ---------------
Amazon EC2            us-west-1     54.215.158.42   <not assigned>
[bright82->cloud[Amazon EC2]]%
```

An allocated static IP can be released with the `staticip release` command in cmsh:

Example

```
[bright82->cloud[Amazon EC2]]% staticip release 54.215.158.42
Releasing static IP 54.215.158.42. Please wait...
Successfully released the static ip.
[bright82->cloud[Amazon EC2]]%
```

Once the IP address has been released, it may no longer be used for instances defined in the custom VPC.

The `staticips` command lists all allocated static IPs for all configured cloud providers.

The `staticip list` command lists static IP addresses for the currently active cloud provider object.

In Bright View, the static IPs can be managed via the clickpath Cloud→AWS Static IPs→Allocate IP.

7.3.4 Subnets With Static IP Addresses In A Custom VPC Recommendation

Subnets can be set up in many ways inside a custom VPC. The following is recommended:

- There must be exactly one network containing all the instances which have static IP addresses. This network should contain the cloud director. The network with the cloud director is arbitrarily referred to as the “public” network.

- There must be zero or more networks containing instances with no static IP addresses assigned to them. Such networks are arbitrarily referred to as the “private” subnets, although the “public” network without an EIP allocation is just as private. Normally the “private” network is intended to be used for regular cloud nodes. It is also possible to move the regular cloud nodes to the “public” network, which is convenient if, for example, packets to the EIP is to be routed to the regular cloud nodes via NAT.

Instances in the private subnets have no static IP addresses assigned to them, so by default they do not communicate with outside networks. To allow them to connect to the outside, the cloud director instance is automatically configured by CMDaemon as a NAT gateway for outside-bound traffic, for the instances existing inside the private subnets.

For example, the cloud director node and regular cloud nodes can be configured inside the us-west-1 network as follows:

Example

```
[bright82->device[us-west-1-director]->interfaces]% list
Type   Network device name IP Network
------- ------------------- --------------
physical eth0 [dhcp] 0.0.0.0 vpc-us-west-1-public
tunnel tun0 [prov] 172.18.255.251 us-west-1
```

Example

© Bright Computing, Inc.
<table>
